Introduction:

.NET framework is developed by Microsoft, provides an environment to run, debug and deploy code onto web services and applications by using tools and functionalities like libraries, classes, and APIs. This framework uses object-oriented programming.

The .NET Framework is a multi-platform software framework developed by Microsoft. .NET developers may handle the performance, testing, security and scalability of web and mobile applications.

Programmers can use the .NET Framework to develop user and business software. They can also coordinate in teams to build programs more effectively.

You can use different languages like C#, Cobol, VB, F#, Perl, etc. for writing .NET framework applications. This Framework supports services, websites, desktop applications, and many more on Windows. It provides functionalities such as generic types, automatic memory management, reflection, concurrency, etc. These functionalities will help to make the development easier and efficiently build high-quality web as well as client applications.

.NET Core is a newer version of the .NET framework and it is a general-purpose, cost-free, open-source development platform developed by Microsoft. .NET Core is a cross-platform framework that runs an application on different operating systems such as Windows, Linux, and macOS operating systems. This framework can be used to develop various kinds of applications like mobile, web, IoT, cloud, microservices, machine learning, game, etc.

Characteristics of .NET Core:

Free and open-source: .NET Core source code project can be obtained from Github. It is free and licensed under the MIT and Apache licenses.

Cross-platform: .NET Core is supported by different operating systems like Windows, macOS, and Linux.

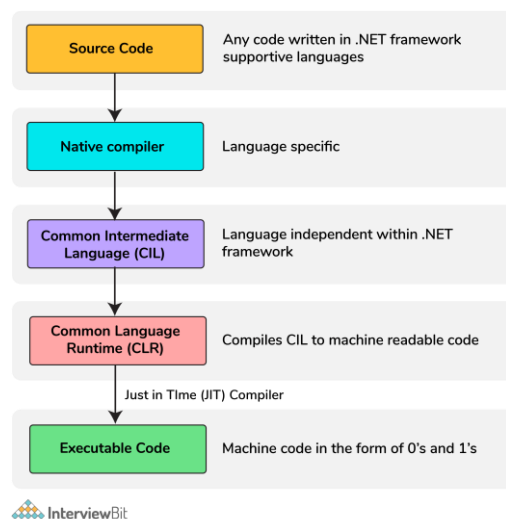

Sharable: A single consistent API model that is written in .NET Standard will be used by .NET Core and is common for all the .NET applications. The same library or API can be used on multiple platforms with different languages.

Friendly: The .NET Core is compatible with .NET Framework, Mono, and Xamarin, through .NET Standard. It also supports working with different Web frameworks and libraries such as Angular, React, and JavaScript.

Fast: .NET Core 3.0 is faster compared to the .NET Framework, .NET Core 2.2 and previous versions. It is also much faster than other server-side frameworks like Node.js and Java Servlet.

1. How does the .NET framework work?

- .NET framework-based applications that are written in supportive languages like C#, F#, or Visual basic are compiled to Common Intermediate Language (CIL).
- Compiled code is stored in the form of an assembly file that has a .dll or .exe file extension.
- When the .NET application runs, Common Language Runtime (CLR) takes the assembly file and converts the CIL into machine code with the help of the Just In Time (JIT) compiler.
- Now, this machine code can execute on the specific architecture of the computer it is running on.

2. Explain about major components of the .NET framework.

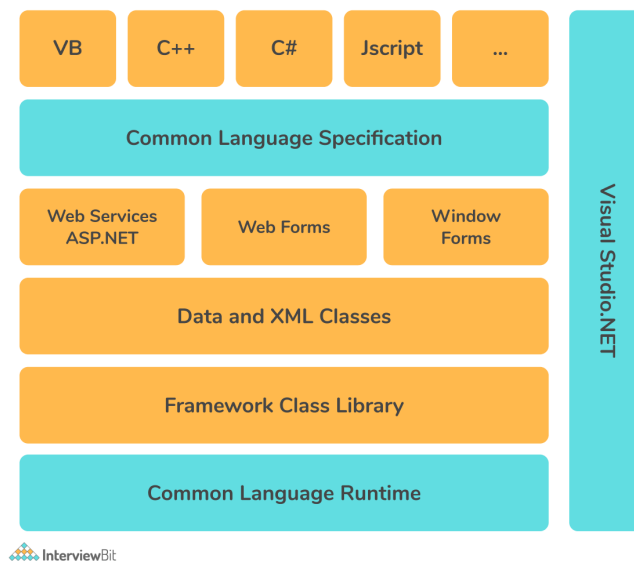

The major components .NET framework are given below:

- **Common Language Runtime(CLR):**
 - It is an execution engine that runs the code and provides services that make the development process easier.
 - Services provided by CLR are memory management, garbage collection, type safety, exception handling, security, and thread management. It also makes it easier for designing the applications and components whose objects interact across the languages.

- The programs written for the .NET Framework are executed by the CLR regardless of programming language. Every .NET Framework version is having CLR.
- **Framework Class Library(FCL):**
 - It has pre-defined methods and properties to implement common and complex functions that can be used by .NET applications. It will also provide types for dates, strings, numbers, etc.
 - This class library includes APIs for database connection, file reading and writing, drawing, etc.
- **Base Class Library(BCL):**
 - The Base Class Library(BCL) has a huge collection of libraries features and functions that are helpful in implementing various programming languages such as C#, F#, Visual C++, etc., in the .NET Framework.
 - BCL is divided into two parts. They are:
 - **User-defined class library:** It includes Assemblies.
 - *Assembly:* A .NET assembly is considered as the major building block of the .NET Framework. An assembly in the CLI(Common Language Infrastructure) is a logical unit of code, which is used for security, deployment, and versioning. Assembly can be defined in two forms namely Dynamic Link Library(.dll) and executable(.exe) files. When compilation of the .NET program takes place, metadata with Microsoft Intermediate Language(MSIL) will be generated and will be stored in a file called Assembly.
 - **Predefined class library:** It contains namespace.
 - *Namespace:* It is the collection of pre-defined methods and classes that are present in the .Net Framework. A namespace can be added to a .NET program with the help of “using system”, where using represents a keyword and system represents a namespace.
- **Common Type System(CTS):**
 - CTS specifies a standard that will mention which type of data and value can be defined and managed in memory during runtime.
 - It will make sure that programming data defined in different languages should interact with each other for sharing the information. For example, in VB.NET we define datatype as integer, while in C# we define int as a data type.
 - It can be used to prevent data loss when you are trying to transfer data from a type in one language to its equivalent type in another language.

- **Common Language Specification (CLS):**

- Common Language Specification (CLS) is a subset of CTS and defines a set of rules and regulations to be followed by every .NET Framework's language.
- A CLS will support inter-operability or cross-language integration, which means it provides a common platform for interacting and sharing information. For example, every programming language(C#, F#, VB .Net, etc.) under the .NET framework has its own syntax. So when statements belonging to different languages get executed, a common platform will be provided by the CLS to interact and share the information.

3. What is an EXE and a DLL?

EXE and DLLs are assembly executable modules.

EXE is an executable file that runs the application for which it is designed. An EXE is produced when we build an application. Therefore the assemblies are loaded directly when we run an EXE. However, an EXE cannot be shared with the other applications.

Dynamic Link Library (DLL) is a library that consists of code that needs to be hidden. The code is encapsulated inside this library. An application can consist of many DLLs which can be shared with the other programs and applications.

4. What is CTS?

CTS stands for **Common Type System**. It follows a set of structured rules according to which a data type should be declared and used in the program code. It is used to describe all the data types that are going to be used in the application.

We can create our own classes and functions by following the rules in the CTS. It helps in calling the data type declared in one programming language by other programming languages.

5. Explain CLS

Common Language Specification (CLS) helps the application developers to use the components that are inter-language compatible with certain rules that come with CLS. It also helps in reusing the code among all of the .NET-compatible languages.

6. What is JIT?

JIT stands for **Just In Time**. It is a compiler that converts the intermediate code into the native language during the execution.

7. What is the difference between int and Int32?

There is no difference between int and Int32. Int32 is a type provided by the .NET framework class whereas int is an alias name for Int32 in the C# programming language.

8. Explain the differences between value type and reference type.

The main differences between value type and reference type are given below:

- A Value Type holds the actual data directly within the memory location and a reference type contains a pointer which consists of the address of another memory location that holds the actual data.
- Value type stores its contents on the stack memory and reference type stores its contents on the heap memory.
- Assigning a value type variable to another variable will copy the value directly and assigning a reference variable to another doesn't copy the value, instead, it creates a second copy of the reference.
- Predefined data types, structures, enums are examples of value types. Classes, Objects, Arrays, Indexers, Interfaces, etc are examples of reference types.

9. What is the difference between managed and unmanaged code?

The main difference between managed and unmanaged code is listed below:

Managed Code	Unmanaged Code
It is managed by CLR.	It is not managed by CLR.
.NET framework is a must for execution.	Does not require a .NET framework for the execution.
Memory management is done through garbage collection.	Runtime environment takes care of memory management.

10. Explain Microsoft Intermediate Language.

MSIL is the Microsoft Intermediate Language, which provides instructions for calling methods, memory handling, storing, and initializing values, exception handling, and so on.

The instructions provided by MSIL are platform-independent and are generated by the language-specific compiler from the source code. JIT compiler compiles the MSIL into machine code based on the requirement.

11. What is an assembly?

An assembly is a file that is automatically generated by the compiler which consists of a collection of types and resources that are built to work together and form a logical unit of functionality. We can also say assembly is a compiled code and logical unit of code.

Assemblies are implemented in the form of executable (.exe) or dynamic link library (.dll) files.

12. Is ASP.NET different from ASP? If yes, explain how?

Yes, ASP.NET and ASP(Active Server Pages) both are different. Let's check how they are different from each other.

- ASP.NET uses .NET languages such as C# and VB.NET, which are compiled to Microsoft Intermediate Language (MSIL). ASP uses VBScript. ASP code is interpreted during the execution.
- ASP.NET which is developed by Microsoft is used to create dynamic web applications while ASP is Microsoft's server-side technology used to create web pages.
- ASP.NET is fully object-oriented but ASP is partially object-oriented.
- ASP.NET has full XML Support for easy data exchange whereas ASP has no built-in support for XML.
- ASP.NET uses the ADO.NET technology to connect and work with databases. ASP uses ADO technology.

13. Explain role-based security in .NET.

Role-based security is used to implement security measures in .NET, based on the roles assigned to the users in the organization. In the organization, authorization of users is done based on their roles.

For example, windows have role-based access like administrators, users, and guests.

You can use Roles, Claims, or Policy.

```
[Authorize(Roles = "Administrator")]
public class AdministrationController : Controller
{
    public IActionResult Index() =>
        Content("Administrator");
}
```

```
[Authorize(Policy = "RequireAdministratorRole")]
public IActionResult Shutdown()
{
    return View();
}
```

14. What is the different type of Constructors?

There are 5 Types of Constructors in C#, they are:

1. Default Constructor

A constructor without any parameters is called a default constructor; in other words, this type of constructor does not take parameters. The drawback of a default constructor is that every instance of the class will be initialized to the same values and it is not possible to initialize each instance of the class with different values.

2. Parameterized Constructor

A constructor with at least one parameter is called a parameterized constructor. The advantage of a parameterized constructor is that you can initialize each instance of the class with a different value.

3. Copy Constructor

The constructor which creates an object by copying variables from another object is called a copy constructor. The purpose of a copy constructor is to initialize a new instance to the values of an existing instance.

4. Private Constructor

When a constructor is created with a private specifier, it is not possible for other classes to derive from this class, neither is it possible to create an instance of this class. They are usually used in classes that contain static members only.

Some key points of a private constructor are:

- One use of a private constructor is when we have only static members.
- It provides an implementation of a singleton class pattern
- Once we provide a constructor that is either private or public or any, the compiler will not add the parameter-less public constructor to the class.

5. Static Constructor

When a constructor is created using a static keyword, it will be invoked only once for all of the instances of the class and it is invoked during the creation of the first instance of the class or the first reference to a static member in the class. A static constructor is used to initialize static fields of the class and to write the code that needs to be executed only once.

Some key points of a static constructor are:

- A static constructor does not take access modifiers or have parameters.
- A static constructor is called automatically to initialize the class before the first instance is created or any static members are referenced.
- A static constructor cannot be called directly.
- The user has no control over when the static constructor is executed in the program.
- A typical use of static constructors is when the class is using a log file and the constructor is used to write entries to this file.

15. Explain the different types of assembly.

Assemblies are classified into 2 types. They are:

Private Assembly:

- It is accessible only to the application.
- We need to copy this private assembly, separately in all application folders where we want to use that assembly. Without copying, we cannot access the private assembly.
- It requires to be installed in the installation directory of the application.

Shared or Public Assembly:

- It can be shared by multiple applications.
- Public assembly does not require copying separately into all application folders. Only one copy of public assembly is required at the system level, we can use the same copy by multiple applications.
- It is installed in the Global Assembly Cache(GAC).

GAC stands for **Global Assembly Cache**. Whenever CLR gets installed on the machine, GAC comes as a part of it. GAC specifically stores those assemblies which will be shared by many applications. A Developer tool called Gacutil.exe is used to add any file to GAC.

16. What is the order of the events in a page life cycle?

There are eight events as given below that take place in an order to successfully render a page:

- Page_PreInit
- Page_Init
- Page_InitComplete
- Page_PreLoad
- Page_Load
- Page_LoadComplete
- Page_PreRender
- Render

17. What is a garbage collector?

Garbage collector frees the unused code objects in the memory. The memory heap is partitioned into 3 generations:

- Generation 0: It holds short-lived objects.
- Generation 1: It stores medium-lived objects.

- Generation 2: This is for long-lived objects.

Collection of garbage refers to checking for objects in the generations of the managed heap that are no longer being used by the application. It also performs the necessary operations to reclaim their memory. The garbage collector must perform a collection in order to free some memory space.

During the garbage collection process:

- The list of live objects is recognized.
- References are updated for the compacted objects.
- The memory space occupied by dead objects is recollected. The remaining objects are moved to an older segment.

System.GC.Collect() method is used to perform garbage collection in .NET.

18. What is caching?

Caching means storing the data temporarily in the memory so that the data can be easily accessed from the memory by an application instead of searching for it in the original location. It increases the speed and performance efficiency of an application.

There are three types of caching:

- Page caching
- Data caching
- Fragment caching

19. Can we apply themes to ASP.NET applications?

Yes. By modifying the following code in the web.config file, we can apply themes to ASP.NET applications:

```
<configuration>
  <system.web>
    <pages theme="windows" />
  </system.web>
</configuration>
```

20. Explain MVC.

MVC stands for Model View Controller. It is an architecture to build .NET applications. Following are three mains logical components of MVC: the model, the view, and the controller.

Fig: Components of MVC

Model: They hold data and its related logic. It handles the object storage and retrieval from the databases for an application. For example:

A Controller object will retrieve the employee information from the database.

It manipulates employee data and sends back to the database or uses it to render the same data.

View: View handles the UI part of an application. They get the information from the models for their display. For example, any employee view will include many components like text boxes, dropdowns, etc.

Controller: They handle the user interactions, figure out the responses for the user input and also render the final output. For instance, the Employee controller will handle all the interactions and inputs from the Employee View and update the database using the Employee Model.

21. What is cross-page posting?

Whenever we click on a submit button on a webpage, the data is stored on the same page. But if the data is stored on a different page and linked to the current one, then it is known as a cross-page posting. Cross-page posting is achieved by POSTBACKURL property.

To get the values that are posted on this page to which the page has been posted, the FindControl method can be used.

22. What is a delegate in .NET?

A delegate is a .NET object which defines a method signature and it can pass a function as a parameter.

Delegate always points to a method that matches its specific signature. Users can encapsulate the reference of a method in a delegate object.

When we pass the delegate object in a program, it will call the referenced method. To create a custom event in a class, we can make use of delegate.

23. What are security controls available on ASP.NET?

Following are the five security controls available on ASP.NET:

- <asp: Login> Provides a login capability that enables the users to enter their credentials with ID and password fields.
- <asp: LoginName> Used to display the user name who has logged-in.
- <asp: LoginView> Provides a variety of views depending on the template that has been selected.
- <asp: LoginStatus> Used to check whether the user is authenticated or not.
- <asp: PasswordRecovery> Sends an email to a user while resetting the password.

24. Explain Difference between Scoped, Singleton, and Transient.

- Transient objects are always different; a new instance is provided to every controller and every service.
- Scoped objects are the same within a request, but different across different requests
- Singleton objects are the same for every object and every request

25. What is boxing and unboxing in .NET?

Boxing is the process of converting a value type into a reference type directly. Boxing is implicit.

Unboxing is the process where reference type is converted back into a value type. Unboxing is explicit.

An example is given below to demonstrate boxing and unboxing operations:

```
int a = 10;           // a value type
object o = a;         // boxing
int b = (int)o;       // unboxing
```

26. What is MIME in .NET?

MIME stands for Multipurpose Internet Mail Extensions. It is the extension of the e-mail protocol which lets users use the protocol to exchange files over emails easily.

Servers insert the MIME header at the beginning of the web transmission to denote that it is a MIME transaction.

Then the clients use this header to select an appropriate 'player' for the type of data that the header indicates. Some of these players are built into the web browser.

27. What is the use of manifest in the .NET framework?

Manifest stores the metadata of the assembly. It contains metadata which is required for many things as given below:

- Assembly version information.
- Scope checking of the assembly.
- Reference validation to classes.

- Security identification.

28. Explain different types of cookies available in ASP.NET?

Two types of cookies are available in ASP.NET. They are:

- **Session Cookie:** It resides on the client machine for a single session and is valid until the user logs out.
- **Persistent Cookie:** It resides on the user machine for a period specified for its expiry. It may be an hour, a day, a month, or never.

29. What is the meaning of CAS in .NET?

Code Access Security(CAS) is necessary to prevent unauthorized access to programs and resources in the runtime. It is designed to solve the issues faced when obtaining code from external sources, which may contain bugs and vulnerabilities that make the user's system vulnerable.

The different components of CAS are Code group, Permissions, and Evidence.

- **Evidence**– To decide and assign permissions, the CAS and CLR depend on the specified evidence by the assembly. The examination of the assembly provides details about the different pieces of evidence. Some common evidence include Zone, URL, Site, Hash Value, Publisher and Application directory.
- **Code Group** – Depending on the evidence, codes are put into different groups. Each group has specific conditions attached to it. Any assembly that matches those condition is put into that group.
- **Permissions** – Each code group can perform only specific actions. They are called Permissions. When CLR loads an assembly, it matches them to one of the code groups and identifies what actions those assemblies can do. Some of the Permissions include Full Trust, Everything, Nothing, Execution, Skip Verification, and the Internet.

CAS gives limited access to code to perform only certain operations instead of providing all at a given point in time. CAS constructs a part of the native .NET security architecture.

30. What is the appSettings section in the web.config file?

We can use the appSettings block in the web.config file, if we want to set the user-defined values for the whole application. Example code given below will make use of ConnectionString for the database connection throughout the project:

```
<em>
  <configuration>
    <appSettings>
      <add key= "ConnectionString" value="server=local;
pwd=password; database=default" />
    </appSettings>
  </configuration>
</em>
```

31. What is the difference between an abstract class and an interface?

The main difference between an abstract class and an interface are listed below:

Abstract Class	Interface
Used to declare properties, events, methods, and fields as well.	Fields cannot be declared using interfaces.
Provides the partial implementation of functionalities that must be implemented by inheriting classes.	Used to declare the behavior of an implementing class.
Different kinds of access modifiers like private, public, protected, etc. are supported.	Only public access modifier is supported.
It can contain static members.	It does not contain static members.
Multiple inheritances cannot be achieved.	Multiple inheritances are achieved.

32. What are the types of memories supported in the .NET framework?

Two types of memories are present in .NET. They are:

Stack: Stack is a stored-value type that keeps track of each executing thread and its location. It is used for static memory allocation.

Heap: Heap is a stored reference type that keeps track of the more precise objects or data. It is used for dynamic memory allocation.

33. Explain localization and globalization.

Localization is the process of customizing our application to behave as per the current culture and locale.

Globalization is the process of designing the application so that it can be used by users from across the globe by supporting multiple languages.

34. What are the parameters that control the connection pooling behaviors?

There are 4 parameters that control the connection pooling behaviours. They are:

- Connect Timeout
- Min Pool Size
- Max Pool Size
- Pooling

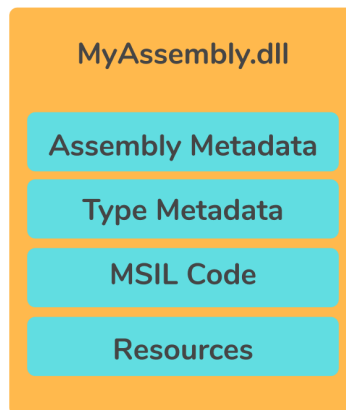

35. What are MDI and SDI?

MDI (Multiple Document Interface): An MDI allows you to open multiple windows, it will have one parent window and as many child windows. The components are shared from the parent window like toolbar, menubar, etc.

SDI (Single Document Interface): SDI opens each document in a separate window. Each window has its own components like a toolbar, menubar, etc. Therefore it is not constrained to the parent window.

36. Explain the different parts of an Assembly.

The different parts of an assembly are:

The different parts of an assembly are:

- **Manifest** – Every static or dynamic assembly holds a data collection that gives details about how the elements in the assembly relate to each other. An assembly manifest consists of complete metadata required to specify version requirements and security identity of an assembly, and also the metadata required for defining the assembly scope and resolving references to classes and resources.
The assembly manifest will be stored in either a standalone PE(Portable Executable) file that holds only assembly manifest information, or in a PE file (a .exe or .dll) with MSIL(Microsoft intermediate language) code.
- **Type Metadata** – Metadata gives you additional information such as types, type names, method names, etc about the contents of an assembly. Metadata will be automatically generated by the Compilers from the source files and the compiler will embed this metadata within target output files like .exe, .dll, or a .netmodule(in the case of multi-module assembly).
- **MSIL** – Microsoft Intermediate Language(MSIL) is a code that implements the types. It includes instructions to load, store, initialize, and call the methods on objects. Along with this, it also includes instructions for control flow, direct memory access, arithmetic and logical operations, exception handling, etc. This is generated by the compiler using one or more source code files. During the runtime, the JIT(Just In Time) compiler of CLR(Common Language Runtime) converts the MSIL code into native code to the Operating System.

- **Resources** – Resources can be a list of related files such as .bmp or .jpg files. These resources are static, which means they do not change during run time. Resources are not executable items.

37. What is .NET core?

.NET Core can be said as the newer version of the .NET Framework. It is a cost-free, general-purpose, open-source application development platform provided by Microsoft. It is a cross-platform framework because it runs on various operating systems such as Windows, Linux, and macOS. This Framework can be used to develop applications like mobile, web, IoT, machine learning, game, cloud, microservices, etc.

It consists of important features like a cross-platform, sharable library, etc., that are necessary for running a basic .NET Core application. The remaining features are supplied in the form of NuGet packages, that can be added to your application according to your needs. Like this we can say, the .NET Core will boost up the performance of an application, decreases the memory footprint, and becomes easier for maintenance of an application. It follows the modular approach, so instead of the entire .NET Framework installation, your application can install or use only what is required.

38. What is .NET Core used for?

- .NET Core is useful in the server application creations, that run on various operating systems like Windows, Mac, and Linux. Using this, developers can write libraries as well as applications in C#, F#, and VB.NET in both runtimes.
- Generally, it is used for cloud applications or for modifying large enterprise applications into microservices.
- .NET Core 3.0 supports cross-development between WPF, UWP, and Windows Forms.
- .NET Core supports microservices, which permits cross-platform services to work with the .NET Core framework including services developed with .NET Framework, Ruby, Java, etc.
- .NET Core's features like lightweight, modularity, and flexibility make it easier to deploy .NET Core applications in containers. These containers can be deployed on any platform, Linux, cloud, and Windows.

39. What are C# and F#?

C# is a general-purpose and object-oriented programming language from Microsoft that runs on the .NET platform. It is designed for CLI(Common Language Infrastructure), which has executable code and a runtime environment that allows for the usage of different high-level languages on various computer platforms and architectures. It is mainly used for developing web applications, desktop applications, mobile applications, database applications, games, etc.

F# is an open-source, functional-first, object-oriented and, cross-platform programming language that runs on a .NET platform and is used for writing robust, succinct, and performant code. We can say that F# is data-oriented because here code involves transforming data with functions. It is mainly used in making scientific models, artificial intelligence research work, mathematical problem solving, financial modelling, GUI games, CPU design, compiler programming, etc.

40. What is CoreCLR?

CoreCLR is the run-time execution engine provided by the .NET Core. It consists of a JIT compiler, garbage collector, low-level classes, and primitive data types. .NET Core is a modular implementation of .NET, and can be used as the base stack for large scenario types, ranging from console utilities to web applications in the cloud.

Here, various programming languages will be compiled by respective compilers (Roslyn can compile both C# and VB code as it includes C# and VB compilers) and Common Intermediate Language (CIL) code will be generated. When the application execution begins, this CIL code is compiled into native machine code by using a JIT compiler included within CoreCLR. This CoreCLR is supported by many operating systems such as Windows, Linux, etc.

41. What is the purpose of webHostBuilder()?

WebHostBuilder function is used for HTTP pipeline creation through `webHostBuilder.Use()` chaining all at once with `WebHostBuilder.Build()` by using the builder pattern. This function is provided by `Microsoft.AspNetCore.Hosting` namespace. The `Build()` method's purpose is building necessary services and a `Microsoft.AspNetCore.Hosting.IWebHost` for hosting a web application.

42. What is Zero Garbage Collectors?

Zero Garbage Collectors allows you for object allocation as this is required by the Execution Engine. Created objects will not get deleted automatically and theoretically, no longer required memory is never reclaimed.

There are two main uses of Zero Garbage Collectors. They are:

- Using this, you can develop your own Garbage Collection mechanism. It provides the necessary functionalities for properly doing the runtime work.
- It can be used in special use cases like very short living applications or almost no memory allocation (concepts such as No-alloc or Zero-alloc programming). In these cases, Garbage Collection overhead is not required and it is better to get rid of it.

43. What is CoreFx?

CoreFX is the set of class library implementations for .NET Core. It includes collection types, console, file systems, XML, JSON, async, etc. It is platform-neutral code, which means it can be shared across all platforms. Platform-neutral code is implemented in the form of a single portable assembly that can be used on all platforms.

44. What is the IGCToCLR interface?

IGCToCLR interface will be passed as an argument to the `InitializeGarbageCollector()` function and it is used for runtime communication. It consists of a lot of built-in methods such as `RestartEE()`, `SuspendEE()`, etc.

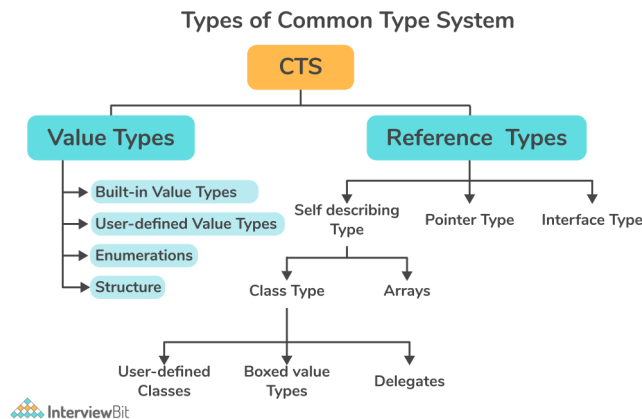

45. What is the use of generating SQL scripts in the .NET core?

It's useful to generate a SQL script, whenever you are trying to debug or deploy your migrations to a production database. The SQL script can be used in the future for reviewing the accuracy of data and tuned to fit the production database requirement.

46. Explain about types of Common Type System(CTS).

Common Type System(CTS) standardizes all the datatypes that can be used by different programming languages under the .NET framework.

CTS has two types. They are:

1. **Value Types:** They contain the values that are stored on a stack or allocated inline within a structure. They are divided into :

- Built-in Value Types - It includes primitive data types such as Boolean, Byte, Char, Int32, etc.
- User-defined Value Types - These are defined by the user in the source code. It can be enumeration or structure.
- Enumerations - It is a set of enumerated values stored in the form of numeric type and are represented by labels.
- Structures - It defines both data(fields of the structure) and the methods(operations performed on that data) of the structure. In .NET, all primitive data types like Boolean, Byte, Char, DateTime, Decimal, etc., are defined as structures.

2. **Reference Types:** It Stores a reference to the memory address of a value and is stored on the heap. They are divided into:

- Interface types - It is used to implement functionalities such as testing for equality, comparing, and sorting, etc.
- Pointer types - It is a variable that holds the address of another variable.
- Self-describing types - It is a data type that gives information about themselves for the sake of garbage collectors. It includes arrays (collection of variables with the same datatype stored under a single name) and class types (they define the operations like methods, properties, or events that are performed by an object and the data that the object contains) like user-defined classes, boxed value types, and delegates(used for event handlers and callback functions).

47. Give the differences between .NET Core and Mono?

.NET Core	Mono
.Net Core is the subset of implementation for the .NET framework by Microsoft itself.	Mono is the complete implementation of the .Net Framework for Linux, Android, and iOS by Xamarin.
.NET Core only permits you to build web applications and console applications.	Mono permits you to build different application types available in .NET Framework, including mobile applications, GUI-enabled desktop apps, etc.
.NET Core does not have the built-in capability to be compiled into WebAssembly-compatible packages.	Mono has the built-in capability to be compiled into WebAssembly-compatible packages.
.NET Core is never intended for gaming. You can only develop a text-based adventure or relatively basic browser-based game using .NET Core.	Mono is intended for the development of Games. Games can be developed using the Unity gaming engine that supports Mono.

48. What is Transfer-encoding?

Transfer-encoding is used for transferring the payload body(information part of the data sent in the HTTP message body) to the user. It is a hop-by-hop header, that is applied not to a resource itself, but to a message between two nodes. Each multi-node connection segment can make use of various Transfer-encoding values.

Transfer-encoding is set to “Chunked” specifying that Hypertext Transfer Protocol’s mechanism of Chunked encoding data transfer is initiated in which data will be sent in a form of a series of “chunks”. This is helpful when the amount of data sent to the client is larger and the total size of the response will not be known until the completion of request processing.

49. Whether 'debug' and 'trace' are the same?

No. The Trace class is used for debugging as well as for certain build releases. It gives execution plan and process timing details. While debug is used mainly for debugging. Debug means going through the program code flow during execution time.

Debug and trace allow for monitoring of the application for errors and exceptions without VS.NET IDE.

50. What is MSBuild in the .NET Core?

MSBuild is the free and open-source development platform for Visual Studio and Microsoft. It is a build tool that is helpful in automating the software product creation process, along with source code compilation, packaging, testing, deployment, and documentation creation. Using MSBuild, we can build Visual Studio projects and solutions without the need of installing the Visual Studio IDE.

In the Universal Windows Platform(UWP) app, if you open the folder named project, you will get to see both files namely project.json and *.csproj. But if you open our previous Console application in .NET Core, you will get to see project.json and *.xproj files.

51. What are Universal Windows Platform(UWP) Apps in .Net Core?

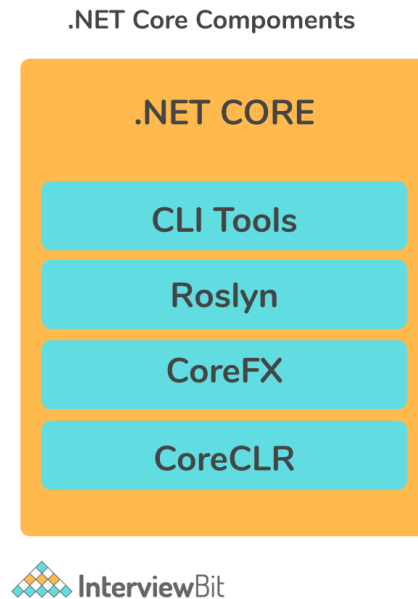

Universal Windows Platform(UWP) is one of the methods used to create client applications for Windows. UWP apps will make use of WinRT APIs for providing powerful UI as well as features of advanced asynchronous that are ideal for devices with internet connections.

Features of UWP apps:

- Secure: UWP apps will specify which resources of device and data are accessed by them.
- It is possible to use a common API on all devices(that run on Windows 10).
- It enables us to use the specific capabilities of the device and adapt the user interface(UI) to different device screen sizes, DPI(Dots Per Inches), and resolutions.
- It is available on the Microsoft Store on all or specified devices that run on Windows 10.
- We can install and uninstall these apps without any risk to the machine/incurring "machine rot".
- Engaging: It uses live tiles, user activities, and push notifications, that interact with the Timeline of Windows as well as with Cortana's Pick Up Where I Left Off, for engaging users.
- It can be programmable in C++, C#, Javascript, and Visual Basic. For UI, you can make use of WinUI, HTML, XAML, or DirectX.

52. Explain about .NET Core Components.

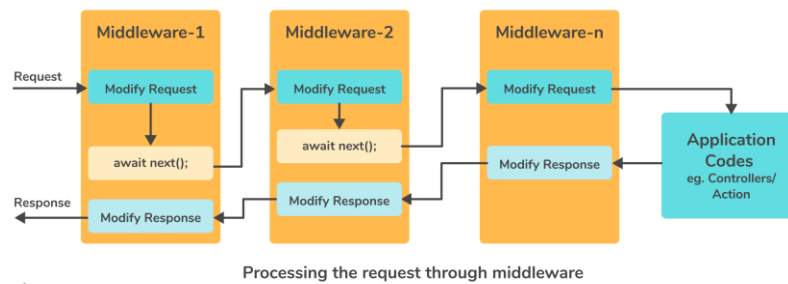

The .NET Core Framework is composed of the following components:

- **CLI Tools:** Command Line Interface (CLI) tools is a cross-platform tool for developing, building, executing, restoring packages, and publishing. It is also capable of building Console applications and class libraries that can run on the entire .NET framework. It is installed along with .NET Core SDK for the selected platforms. So it does not require separate installation on the development machine. We can verify for the proper CLI installation by typing dotnet on the command prompt of Windows and then pressing Enter. If usage and help-related texts are displayed, then we can conclude that CLI is installed properly.
- **Roslyn (.NET Compiler platform):** It is a set of an open-source language compiler and also has code analysis API for the C# and Visual Basic ([VB.NET](#)) programming languages. Roslyn exposes modules for dynamic compilation to Common Intermediate Language (CLI), syntactic (lexical) and semantic code analysis, and also code emission.
- **CoreFX:** CoreFX is a set of framework libraries. It consists of the new BCL (Base Class Library) i.e. System.* things like System.Xml, System.Collections, etc.
- **CoreCLR:** A JIT(Just In Time) based CLR (Command Language Runtime). CoreCLR is the runtime implementation that runs on cross-platform and has the GC, RyuJIT, native interop, etc.

53. What is middleware in .NET core?

- Middleware is software assembled into an application pipeline for request and response handling. Each component will choose whether the request should be passed to the next component within the pipeline, also it can carry out work before and after the next component within the pipeline.
- For example, we can have a middleware component for user authentication, another middleware for handling errors, and one more middleware for serving static files like JavaScript files, images, CSS files, etc.
- It can be built-in into the .NET Core framework, which can be added through NuGet packages. These middleware components are built as part of the configure method's application startup class. In the [ASP.NET](#) Core application, these Configure methods will set up a request processing pipeline. It contains a sequence of request delegates that are called one after another.
- Normally, each middleware will handle the incoming requests and passes the response to the next middleware for processing. A middleware component can take the decision of not calling the next middleware in the pipeline. This process is known as short-circuiting the pipeline or terminating the request pipeline. This process is very helpful as it avoids unnecessary work. For example, if the request is made for a static file such as a CSS file, image, or JavaScript file, etc., these static files middleware can process and serve the request and thus short-circuit the remaining pipeline.

InterviewBit

Here, there are three middlewares associated with an ASP.NET Core web application. They can be either middleware provided by the framework, added through NuGet, or your own custom middleware. The HTTP request will be added or modified by each middleware and control will be optionally passed to the next middleware and a final response will be generated on the execution of all middleware components.

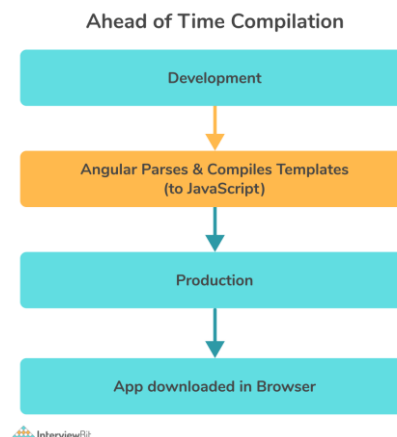

54. Differentiate .NET Core vs .NET framework.

Features	.NET Core	.NET framework
Compatibility	It works based on the principle of “build once, run anywhere”. It is cross-platform, so it is compatible with different operating systems such as Linux, Windows, and Mac OS.	This framework is compatible with the Windows operating system only. Even though, it was developed for supporting software and applications on all operating systems.
Installation	Since it is cross-platform, it is packaged and installed independently of the OS.	It is installed in the form of a single package for Windows OS.
Application Models	It does not support developing the desktop application and it focuses mainly on the windows mobile, web, and windows store.	It is used for developing both desktop and web applications, along with that it also supports windows forms and WPF applications.
Performance and Scalability	It provides high performance and scalability.	It is less effective compared to .Net Core in terms of performance as well as scalability of applications.
Support for Micro-Services and REST Services	It supports developing and implementing the micro-services and the user is required to create a REST API for its implementation.	It does not support the microservices’ development and implementation, but it supports REST API services.
Packaging and Shipping	It is shipped as a collection of Nugget packages.	All the libraries that belong to the .Net Framework are packaged and shipped all at once.
Android Development	It is compatible with open-source mobile app platforms like Xamarin, via .NET Standard Library. Developers can make use of tools of Xamarin for configuring the mobile application for particular mobile devices like Android, iOS, and Windows phones.	It does not support the development of mobile applications.
CLI Tools	For all supported platforms, it provides lightweight editors along with command-line tools.	This framework is heavy for CLI(Command Line Interface) and developers usually prefer to work on the lightweight CLI.

Features	.NET Core	.NET framework
Deployment Model	Updated version of the .NET Core gets initiated on one machine at a time, which means it gets updated in new folders/directories in the existing application without affecting it. Thus, we can say that .NET Core has a very good flexible deployment model.	When the updated version is released, it is deployed only on the Internet Information Server at first.

55. Explain Explicit Compilation (Ahead of Time compilation).

- Ahead-of-time (AOT) compilation is the process of compiling a high-level language into a low-level language during build-time, i.e., before program execution. AOT compilation reduces the workload during run time.
- AOT provides faster start-up time, in larger applications where most of the code executes on startup. But it needs more amount of disk space and memory or virtual address space to hold both IL(Intermediate Language) and precompiled images. In this case, the JIT(Just In Time) Compiler will do a lot of work like disk I/O actions, which are expensive.
- The explicit compilation will convert the upper-level language into object code on the execution of the program. Ahead of time(AOT) compilers are designed for ensuring whether the CPU will understand line-by-line code before doing any interaction with it.
- Ahead-of-Time (AOT) compilation happens only once during build time and it does not require shipping the HTML templates and the Angular compiler into the bundle. The source code generated can begin running immediately after it has been downloaded into the browser, earlier steps are not required. The AOT compilation will turn the HTML template into the runnable code fragment. AOT will analyze and compile our templates statically during build time.

Benefits of AOT Compilation:

- Application size is smaller because the Compiler itself isn't shipped and unused features can be removed.
- Template the parse errors that are detected previously(during build time)
- Security is high (not required to dynamically evaluate templates)
- Rendering of a component is faster (pre-compiled templates)
- For AOT compilation, some tools are required to accomplish it automatically in the build process.

56. What is MEF?

The MEF (Managed Extensibility Framework) is a library that is useful for developing extensible and lightweight applications. It permits application developers for using extensions without the need for configuration. It also allows extension developers for easier code encapsulation and thus avoiding fragile hard dependencies. MEF will let you reuse the extensions within applications, as well as across the applications. It is an integral part of the .NET Framework 4. It improves the maintainability, flexibility, and testability of large applications.

57. In what situations .NET Core and .NET Standard Class Library project types will be used?

.NET Core library is used if there is a requirement to increase the surface area of the .NET API which your library will access and permit only applications of .NET Core to be compatible with your library if you are okay with it.

.NET Standard library will be used in case you need to increase the count of applications that are compatible with your library and reduce surface area(a piece of code that a user can interact with) of the .NET API which your library can access if you are okay with it.

58. What is CoreRT?

- CoreRT is the native runtime for the compilation of .NET natively ahead of time and it is a part of the new .NET Native (as announced in April 2014).
- It is not a virtual machine and it does not have the facility of generating and running the code on the fly as it doesn't include a JIT. It has the ability for RTTI(run-time type identification) and reflection, along with that it has GC(Garbage Collector).
- The type system of the CoreRT is designed in such a way that metadata for reflection is not at all required. This feature enables to have an AOT toolchain that can link away unused metadata and can identify unused application code.

59. What is .NET Core SDK?

.NET Core SDK is a set of tools and libraries that allows the developer to create a .NET application and library for .NET 5 (also .NET Core) and later versions. It includes the .NET CLI for building applications,

.NET libraries and runtime for the purpose of building and running apps, and the dotnet.exe(dotnet executable) that runs CLI commands and runs an application. Here's the [link to download](#).

60. What is Docker?

- Docker is an open-source platform for the development of applications, and also for shipping and running them. It allows for separating the application from the infrastructure using containers so that software can be delivered quickly. With Docker, you will be able to manage the infrastructure in the same ways you used to manage your applications.
- It supports shipping, testing, and deploying application code quickly, thus reducing the delay between code writing and running it in production.
- The Docker platform provides the ability of packaging and application execution in a loosely isolated environment namely container. The isolation and security permit you for running multiple containers at the same time on a given host. Containers are lightweight and they include every necessary thing required for running an application, so you need not depend on what is currently installed within the host.

61. What is Xamarin?

- Xamarin is an open-source platform useful in developing a modern and efficient application for iOS, Android, and Windows with .NET. It is an abstraction layer used to manage the communication of shared code with fundamental platform code.
- Xamarin runs in a managed environment that gives benefits like garbage collection and memory allocation.
- Developers can share about 90% of their applications over platforms using Xamarin. This pattern permits developers for writing entire business logic in a single language (or reusing existing app code) but accomplish native performance, look and feel on each platform. The Xamarin applications can be written on Mac or PC and then they will be compiled into native application packages, like a .ipa file on iOS, or .apk file on Android.

62. How can you differentiate ASP.NET Core from .NET Core?

.NET Core is a runtime and is used for the execution of an application that is built for it. Whereas ASP.NET Core is a collection of libraries that will form a framework for developing web applications. ASP.NET Core libraries can be used on .NET Core as well as on the “Full .NET Framework”.

An application using the tools and libraries of ASP.NET Core is normally referred to as “ASP.NET Core Application”, which in theory doesn’t say whether it is built for .NET Framework or .NET Core. So an application of “ASP.NET Core” can be considered as a “.NET Core Application” or a “.NET Framework Application”.

63. Write a program to calculate the addition of two numbers.

The steps are as follows:

1. You need to create a new ASP.NET Core Project “CalculateSum”. Open Visual Studio 2015, goto **File-> New-> Project**. Select the option Web in Left Pane and go for the option **ASP.NET Core Web**

Application (.NET Core) under the central pane. Edit the project name as “CalculateSum” and click on OK.

2. In the template window, select Web Application and set the Authentication into “No Authentication” and click on OK.

3. Open “Solution Explorer” and right-click on the folder “Home” (It is Under Views), then click on **Add New Item**. You need to select **MVC View Page Template** under ASP.NET Section and rename it as “addition.cshtml” and then click on the **Add** button.

4. Open addition.cshtml and write the following code:

```
@{
    ViewBag.Title = "Addition Page";
}
<h1>Welcome to Addition Page</h1>
<form asp-controller="Home" asp-action="add" method="post">
    <span>Enter First Number : </span> <input id="Text1" type="text"
name="txtFirstNum" /> <br /><br />
    <span>Enter Second Number : </span> <input id="Text2" type="text"
name="txtSecondNum" /> <br /><br />
    <input id="Submit1" type="submit" value="Add" />
</form>
<h2>@ViewBag.Result</h2>
```

Here, we have created a simple form that is having two text boxes and a single Add Button. The text boxes are named as txtFirstNum and txtSecondNum. On the controller page, we can access these textboxes using:

```
<form asp-controller="Home" asp-action="add" method="post">
```

This form will indicate all the submissions will be moved to HomeController and the method add action will be executed.

5. Open the HomeController.cs and write the following code onto it:

```
using System;
using Microsoft.AspNetCore.Mvc;

namespace CalculateSum.Controllers
{
    public class HomeController : Controller
    {
        public IActionResult Index()
        {
            return View();
        }
        public IActionResult About()
        {
            ViewData["Message"] = "Application description page.";
            return View();
        }
    }
}
```

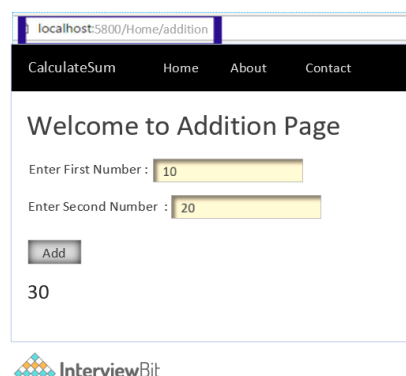

```

public IActionResult Contact()
{
    ViewData["Message"] = "Contact page.";
    return View();
}
public IActionResult Error()
{
    return View();
}
public IActionResult addition()
{
    return View();
}
[HttpPost]
public IActionResult add()
{
    int number1 =
Convert.ToInt32 (HttpContext.Request.Form["txtFirstNum"].ToString());
    int number2 =
Convert.ToInt32 (HttpContext.Request.Form["txtSecondNum"].ToString());
    int res = number1 + number2;
    ViewBag.Result = res.ToString();
    return View("addition");
}
}
}

```

In this program, we have added two IAction Methods addition() and add(). Addition() method will return the addition view page and add() method obtains input from the browser, processes it, and results will be kept in ViewBag.Result and then returned to the browser.

Now, press Ctrl+F5 for running your program. This will launch an [ASP.NET](#) Core website into the browser. Add /Home/addition at the end of the link and then hit on enter. The output format is given below:

64. Why do we use Response.Output.Write()?

Response.Output.Write() is used to get the formatted output.

65. What is the difference between Response.Redirect and Server.Transfer?

Response.Redirect basically redirects the user's browser to another page or site. The history of the user's browser is updated to reflect the new address as well. It also performs a trip back to the client where the client's browser is redirected to the new page.

Whereas, Server.Transfer transfers from one page to the other without making any round-trip back to the client's browser. The history does not get updated in the case of Server.Transfer.

66. Explain the difference between a class and an object?

Class	Object
Class is the definition of an object	An object is an instance of a class.
It is a template of the object	A class does not become an object unless instantiated
It describes all the methods, properties, etc	An object is used to access all those properties from the class.

67. Differentiate between constants and read-only variables.

Constants	Read-only Variables
Evaluated at compile time	Evaluated at run-time
Support only value type variables	They can hold the reference type variables
They are used when the value is not changing at compile time	Used when the actual value is unknown before the run-time
Cannot be initialized at the time of declaration or in a constructor	Can be initialized at the time of declaration or in a constructor

68. What is the difference between custom and user control?

Custom Control	User Control
Derives from control	Derives from UserControl
Dynamic Layout	Static Layout
Defines a single control	Defines a set of con
It has full toolbox support	Cannot be added to the toolbox
Loosely coupled control	Tightly coupled control

69. What is the application domain?

ASP.NET introduces a concept of application domain or AppDomain which is like a lightweight process that acts like both container and boundary. The .NET run-time uses the AppDomain as a container for data and code. The CLR allows multiple .NET applications to run in a single AppDomain.

70. What are the different validators in ASP.NET?

- **Client-side validation** – When the validation takes place on the client-side browser, it is called client-side validation. Usually, JavaScript is used for client-side validation.
- **Server-side validation** – When the validation takes place on the server then it is called server-side validation. Server-side validation is considered as a secure form of validation because even if the user bypasses the client-side validation we can still catch it in server-side validation.

71. What is the difference between function and stored procedure?

Function	Stored Procedure
Must return a single value	Always used to perform a specific task
It can only have the input parameter	It can have both input and output parameters
Exception handling is not possible using a try-catch block	Exception handling can be done using a try-catch block
A stored procedure cannot be called from a function	A function can be called from a procedure

72. Explain passport authentication.

During the passport authentication, it first checks the passport authentication cookie, if the cookie is not available the application redirects to the passport sign on page. Passport service then authenticates the details of the user on the sign on page and if they are valid, stores them on the client machine and then redirects the user to the requested page.

73. List all the templates of the Repeater control.

- ItemTemplate
- AlternatingItemTemplate
- SeparatorTemplate
- HeaderTemplate
- FooterTemplate

74. What is HTTP Handler?

Every request into an ASP.NET application is handled by a specialized component called HTTP handler. It is the most important component for handling ASP.NET application requests.

It uses different handlers to serve different files. The handler for web page creates the page and control objects, runs your code and then renders the final HTML.

Following are the default HTTP handlers for ASP.NET:

- Page Handler(.aspx): Handles web pages
- User Control Handler(.ascx): It handles web user control pages
- Web Service Handler(.asmx): Handles web service pages
- Trace Handler(trace.axd): It handles trace functionality

75. What is the allowed Methods in HTTP requests?

- GET retrieves the representation of the resource at a specified URI. GET should have no side effects on the server.
- PUT updates a resource at a specified URI (replaces the entire resource). PUT can also be used to create a new resource at a specified URI, if the server allows clients to specify new URIs.
- PATCH updates exactly like PUT, however it doesn't require to replace the entire entity, Only the specified property will be changed (no need to represent the whole entity).
- POST creates a new resource. The server assigns the URI for the new object and returns this URI as part of the response message.
- DELETE deletes a resource at a specified URI.

76. What is the difference between ExecuteScalar and ExecuteNonQuery?

ExecuteScalar	ExecuteNonQuery
Returns the output value	Does not return any value
Used for fetching a single value	Used to execute insert and update statements
Does not return the number of affected rows	Returns the number of affected rows.

77. Explain what inheritance is, and why it's important.

Inheritance is one of the most important concepts in object-oriented programming, together with encapsulation and polymorphism. Inheritance allows developers to create new classes that reuse, extend, and modify the behavior defined in other classes. This enables code reuse and speeds up development. With inheritance, developers can write and debug one class only once, and then reuse that same code as the basis for the new classes. The class whose members are inherited is called the base class, and the class that inherits those members is called the derived class. By default, all classes in .NET are inheritable.

78. Explain the difference between the while and for loop. Provide a .NET syntax for both loops.

Both loops are used when a unit of code needs to execute repeatedly. The difference is that the for loop is used when you know how many times you need to iterate through the code. On the other hand, the while loop is used when you need to repeat something until a given statement is true.

The syntax of the while loop in C# is:

```
while (condition [is true])
{
    // statements
}
```

The syntax of the for loop in C# is:

```
for (initializer; condition; iterator)
{
    // statements
}
```

79. Explain deferred execution vs. immediate execution in LINQ. Provide examples.

In LINQ, deferred execution simply means that the query is not executed at the time it is specified. Specifically, this is accomplished by assigning the query to a variable. When this is done, the query definition is stored in the variable but the query is not executed until the query variable is iterated over. For example:

```
DataContext productContext = new DataContext();

var productQuery = from product in productContext.Products
    where product.Type == "SOAPS"
    select product;    // Query is NOT executed here

foreach (var product in productQuery)    // Query executes HERE
{
    Console.WriteLine(product.Name);
}
```

You can also force **immediate execution** of a query. This can be useful, for example, if the database is being updated frequently, and it is important in the logic of your program to ensure that the results you're accessing are those returned at the point in your code where the query was specified. Immediate execution is often forced using a method such as Average, Sum, Count, List, ToList, or ToArray. For example:

```
DataContext productContext = new DataContext();

var productCountQuery = (from product in productContext.Products
    where product.Type == "SOAPS"
    select product).Count();    // Query executes HERE
```

80. Explain State management in ASP .Net.

Answer: State Management means maintaining the state of the object. The object here refers to a web page/control.

There are two types of State management, Client Side, and Server side.

- Client-Side – Storing the information in the Page or Client's System. They are reusable, simple objects.
- Server Side – Storing the information on the Server. It is easier to maintain the information on the Server rather than depending on the client for preserving the state.

81. What is the difference between trace and debug?

Debug class is used to debug builds while Trace is used for both debug and release builds.

82. What are differences between `system.stringbuilder` and `system.string`?

The main differences between `system.stringbuilder` and `system.string` are:

- `system.stringbuilder` is a mutable while `system.string` is immutable.
- Append keyword is used in `system.stringbuilder` but not in `system.string`.
- `StringBuilder` is more suitable for always-changing strings, Due to not overloading the heap. As `StringBuilder` executes significantly faster than the `String` class when performing the concatenation or modification operations.

83. What is the difference between session object and application object?

The session object is used to maintain the session of each user.

For example: If a user enters into the application then he will get a session id. If he leaves from the application then the session id is deleted. If he again enters into the application, he will get a different session id.

But in the case of application object the id is maintained for whole application.

84. What are the advantages of using session?

- A session stores user states and data to all over the application.

- It is very easy to implement and we can store any kind of object.
- It can store every user data separately.
- Session is secure and transparent from user because session object is stored on the server.

85. What are the disadvantages of using session?

- Performance overhead occurs in case of large number of users, because session data is stored in server memory.
- Overhead involved in serializing and De-Serializing session Data. Because In case of StateServer and SQLServer session mode we need to serialize the object before store.

86. Can you set the session out time manually?

Yes. Session out time can be set manually in web.config.

87. How to retrieve username in case of Window Authentication?

System.Environment.UserName

88. What is the difference between Hash table and Array list?

Hash table stores data in the form of value pair and name while Array list stores only values.

You need to pass name to access value from the Hash table while in Array, you need to pass index number to access value.

In Array, you can store only similar type of data type while in Hash table you can store different type of data types. ex. int, string etc.

89. What is the meaning of Immutable?

Immutable means once you create a thing, you cannot modify it.

For example: If you want give new value to old value then it will discard the old value and create new instance in memory to hold the new value.

90. What are the memory-mapped files?

Memory-mapped files are used to map the content of a file to the logical address of an application. It makes you able to run multiple process on the same machine to share data with each other. To obtain a memory mapped file object, you can use the method `MemoryMappedFile.CreateFromFile()`. It represents a persistent memory-mapped file from a file on disk.

91. What is the difference between dispose() and finalize()?

Although Dispose and Finalize both methods are used by CLR to perform garbage collection of runtime objects of .NET applications but there is a difference between them.

The Finalize method is called automatically by the runtime while the Dispose method is called by the programmer. The dispose() method is defined inside the interface IDisposable whereas, the method finalize() is defined inside the class object. The main difference between dispose() and finalize() is that the method **dispose()** has to be explicitly invoked by the programmer whereas, the method **finalize()** is invoked by the garbage collector, just before the object is destroyed.

92. What are cookies?

A cookie is a small amount of data created by server on the client. When a web server creates a cookie, an additional HTTP header is sent to the browser when a page is served to the browser.

93. What are the disadvantages of cookies?

The main disadvantages of cookies are:

- Cookie can store only string value.
- Cookies are browser dependent.
- Cookies are not secure.
- Cookies can store only small amount of data.

94. What are tuples in .Net?

A tuple is a fixed-size collection that can have elements of either same or different data types. The user must have to specify the size of a tuple at the time of declaration just like arrays.

95. How many elements a tuple can hold?

A tuple can hold up from 1 to 8 elements. In the case of more than 8 elements, then the 8th element can be defined as another tuple. Tuples can be specified as parameter or return type of a method.

96. Which architecture does a Dataset follow?

A Dataset follows the disconnected data architecture.

97. How do you check whether a DataReader is closed or opened?

There is a property named "IsClosed" property is used to check whether a DataReader is closed or opened. This property returns a true value if a Data Reader is closed, otherwise a false value is returned.

98. What are the basic requirements for connection pooling?

The following two requirements must be fulfilled for connection pooling:

- There must be multiple processes to share the same connection describing the same parameters and security settings.
- The connection string must be identical.

99. Which properties are used to bind a DataGridView control?

The DataSource property and the DataMember property are used to bind a DataGridView control.

100. What is the different types of classes that is available in C#?

- **Static class:**

A class with a static keyword that contains only static members is defined as a static class. A static class cannot be instantiated.

Characteristics of static class in C#:

- Static class cannot be instantiated using a new keyword.
- Static items can only access other static items. For example, a static class can only contain static members, e.g., variables, methods, etc.
- A static method can only contain static variables and can only access other static items.
- Static items share the resources between multiple users.
- Static cannot be used with indexers, destructors, or types other than classes.
- A static constructor in a non-static class runs only once when the class is instantiated for the first time.
- A static constructor in a static class runs only once when any of its static members are accessed for the first time.
- Static members are allocated in a high-frequency heap area of the memory.

- **Abstract class:**

A class with an abstract modifier indicates that the class is abstract. An abstract class cannot be instantiated. The purpose of an abstract class is to provide a common definition of a base class that multiple derived classes can share.

Characteristics of Abstract class:

- An abstract class cannot be instantiated.
- An abstract class may contain abstract methods and accessors.
- Modifying an abstract class with the sealed modifier is impossible because the two modifiers have opposite meanings. The sealed modifier prevents a class from being inherited, and the abstract modifier requires a class to be inherited.
- A non-abstract class derived from an abstract class must include actual implementations of all inherited abstract methods and accessors.

- **Partial class:**

The partial keyword indicates that other parts of the class, struct, or interface can be defined in the namespace. All the parts must use the partial keyword. All the parts must be available at compile time to form the final type. All the parts must have the same accessibility, such as public, private, and so on.

Characteristics of Partial class:

- All the partial class definitions must be in the same assembly and namespace.
- All the parts must have the same accessibility, public or private, etc.
- If any part is declared abstract, sealed, or base type, then the whole class is declared of the same type.
- Different parts can have different base types, so the final class inherits all the base types.

- The Partial modifier can only appear immediately before the keywords class, struct, or interface.
- Nested partial types are allowed.
- **Sealed class:**
A class with a sealed keyword indicates that the class is sealed to prevent inheritance. A sealed class cannot be inherited.
Note that you can limit specific Methods by applying the keyword sealed before them.

101. What are the different types of indexes in SQL Server?

- **Clustered Index:**
 - Clustered Index stores and sort rows of data in a view or table depending on their central values. There may be an instance of having just one clustered index in each table, as it can empower the client to store data in a solitary request.
 - At the point when a table contains a clustering in SQL server, it is named a clustered table. A clustered index is liked to utilize when adjustment of gigantic information is needed in any data set. If the data put away in a table or data set are not organized in descending or ascending request, at that point, the data table is named as a heap.
- **Non-Clustered Index:**
 - It represents a structure, which is isolated from data rows. This types of indexes in SQL server covers the non-clustered key values, and each worth pair has a pointer to the data row that comprises vital significance.
 - Clustered vs. Non-clustered index in SQL server is that the non-clustered index stores the data at one area and indices at another area, while the clustered index is a kind of index that sorts the data rows in the table on their key values.
- **Column Store Index:**
 - A column store index is one of the types of indexes in SQL Server that has a standard type of index with regards to putting away and questioning enormous data warehousing truth tables. This is an index of SQL, which was intended for development in the presentation of inquiry in the event of jobs with huge measures of data.
 - The column-store index empowers putting away information inside little impressions, which helps in speeding up. The use of this index takes into account the client to get IO with multiple times higher inquiry execution when contrasted with conventional column arranged capacity.
- **Filtered Index:**
 - A filtered index is one of the types of indexes in an SQL server that is made when a column has just a few applicable numbers for questions on the subset of values. If, when a table comprises heterogeneous data rows, a separated list is made in SQL for at least one sort of data.
- **Hash Index:**
 - Hash Index is one of the types of indexes in SQL server that slots containing a pointer or an array of N buckets and a row on each slot or bucket. It utilizes the Hash function $F(K, N)$, where N is several buckets and K is critical. The capacity delineates the key relating to the bucket of the hash index. Every bucket of the Hash Index comprises eight bytes,

which are utilized to stock the memory address of the connected rundown of basic sections.

- **Unique Index:**

- The unique index in the SQL server confirms and guarantees that the index key doesn't contain any copy esteems and along these lines, empowers the clients to examine that each row in the table is exceptional in either way.
- The unique index in SQL is extraordinarily utilized when the client needs to have an extraordinary trait of every information. It permits people to guarantee the data respectability of each characterized section of the table in the data set. This index likewise gives extra data about the data table, which is useful to question enhancers.

102. How to make a property write access allowed only inside its type and read only outside?

We can set the access modifier of GET as public, and the SET as private.

103. Difference between Static & Dynamic polymorphism?

Static polymorphism → Compile-Time/Early-Binding/Method Overloading (same class)

Dynamic polymorphism → Run-Time/Late-Binding/Method Overriding (inherited class)

104. What is method signature?

Methods are declared in a class, struct, or interface by specifying the access level such as public or private, optional modifiers such as abstract or sealed, the return value, the name of the method, and any method parameters. These parts together are the signature of the method.

105. Can you override a function without it declared as virtual/abstract? If not, is there a solution?

To override a method, it must be declared as abstract, virtual or override. So, it will NOT be possible, unless you hide the parent implementation with NEW keyword in the derived class.

106. Are private members inherited in C#?

Technically, they are in the inherited class for functions that depend on them to work properly.

Practically, you can't access them even without reflection.

107. Do you override or overload constructors in C#?

We can't override constructors because they are not inherited.

However, we can overload them.

108. Difference between implicit and explicit type casting?

Implicit is type safe with no data loss and is done when converting from derived class to base class.

Explicit is needed when there is a chance of data loss, and the compiler needs you to outline the conversion (either by specific the exact type to convert to or with using helper class)

109. Compare each datatype with its size in bytes? →

C# Datatype	Bytes	Range
byte	1	0 to 255
sbyte	1	-128 to 127
short	2	-32,768 to 32,767
ushort	2	0 to 65,535
int	4	-2 billion to 2 billion
uint	4	0 to 4 billion
long	8	-9 quintillion to 9 quintillion
ulong	8	0 to 18 quintillion
float	4	7 significant digits ¹
double	8	15 significant digits ²
object	4 byte address	All C# Objects
char	2	Unicode characters
string	4 byte address	Length up to 2 billion bytes ³
decimal	24	28 to 29 significant digits ⁴
bool	1	true, false ⁵
DateTime	8	0:00:00am 1/1/01 to 11:59:59pm 12/31/9999
DateSpan		-10675199.02:48:05.4775808 to 10675199.02:48:05.4775807 ⁶

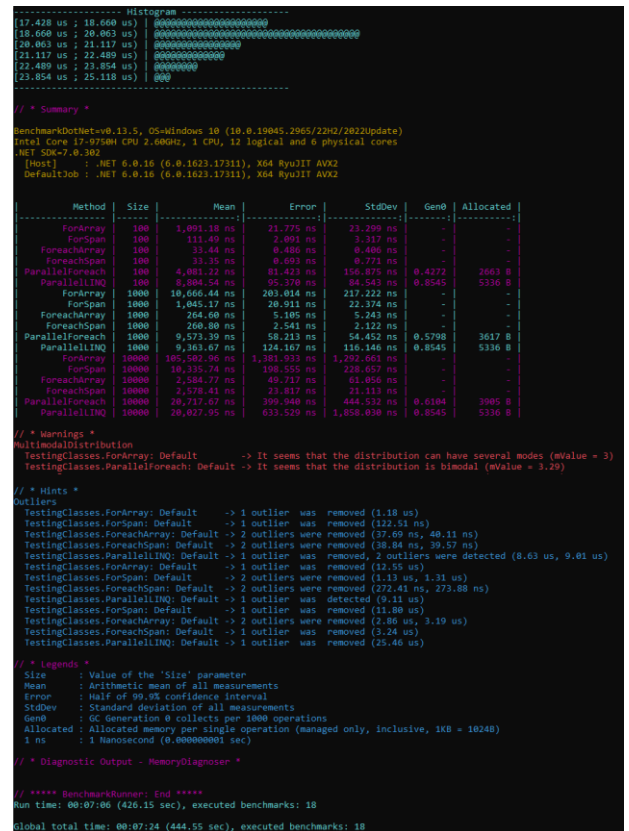

110. What is a Span?

Span<T> is a ref struct that is allocated on the stack rather than on the managed heap. Ref struct types have several restrictions to ensure that they cannot be promoted to the managed heap, including that they can't be boxed, they can't be assigned to variables of type Object, dynamic or to any interface type, they can't be fields in a reference type, and they can't be used across await and yield boundaries. In addition, calls to two methods, Equals(Object) and GetHashCode, throw a NotSupportedException.

111. Order each loop of the following by lowest execution time (fastest): For, ForSpan, ParallelForeach & ParallelLINQ?

From fastest to slowest: For with Span → For with Array → Parallel Linq (Specially with bigger data) → Parallel Foreach (For smaller data, Faster than LINQ)

112. Where are the best places to initialize static data member when creating instance of a class?

In my opinion, they should be inside static class constructor or static methods executed by either static constructor or instance constructors.

113. Can you make a try..finally block without catch block?

Yes it is allowed and will run (finally block will still get executed whether there is an exception or not – unless process is killed, stack overflow, out of memory or an exception in the finally block itself). However, if there happens to be an exception, the finally block will be executed as well and the exception will propagate up the call stack (into the caller method).

114. What is the difference between in, ref, and out?

ref is used to state that the parameter passed may be modified by the method.

in is used to state that the parameter passed cannot be modified by the method.

out is used to state that the parameter passed must be modified by the method.

Both ref and in require initialized parameter, out doesn't require and shouldn't be initialized.

115. What is discard feature in C# 7.0?

A new feature that allows you to create local variables which you can assign but cannot read from “write-only local variables”. (used when you want to pass a parameter to a method and interested only in the output not the parameter, explained in this screenshot) →

Sometimes you need a method, but only need some of the output. If you don't use the discard, then when someone else reads the code, they might wonder what you did with it or why you used that. With a discard, it's obvious. It's not necessary, but it's a nice thing to have when you don't care about an output, you want to be explicit, and don't want to think of a clever handle. – Kevin Fichter Feb 25, 2018 at 5:00

It's not `bool.TryParse("TRUE", out bool _)` but `bool.TryParse("TRUE", out _)`. The 'variable' already exists and you can assign anything to it if you don't want to use it. You can create method with `out` parametr and you don't need to create overloading methods without it, when the calling code can easily discard the result of out parameter using discards. – Gh61 Apr 20, 2022 at 8:06

116. Are delegates in .NET simple or multicast?

Delegates in .NET are multicast delegates. Regardless of whether you choose to attach zero or one or several handlers to them, they are still multicast delegates.

117. Show the difference between Eager-Loading & Lazy-Loading (in EntityFramework)?

Eager Loading helps you to load all your needed entities at once, i.e., all your child entities will be loaded at single database call. This can be achieved, using the Include method, which returns the related entities as a part of the query and a large amount of data is loaded at once.

Lazy Loading is the default behavior of an Entity Framework, where a child entity is loaded only when it is accessed for the first time. It simply delays the loading of the related data, until you ask for it.

118. What are Application Domains?

Application domains provide an isolation boundary for security, reliability, and versioning, and for unloading assemblies. Application domains are typically created by runtime hosts, which are responsible for bootstrapping the common language runtime before an application is run.

A thread is the operating system construct used by the common language runtime to execute code. At run time, all managed code is loaded into an application domain and is run by one or more managed threads.

An application domain is a logical isolation boundary created around .NET applications so that applications do not access or affect each other. It is a light-weight process having its own set of code, data, and configuration settings. Application domains are created by the runtime hosts, which are invoked by the common language runtime (CLR) to load the applications that need to be executed.

119. Compare Socket Communication (WebSocket) & Restful API Calls?

WebSocket is a real-time protocol that enables full-duplex, bidirectional communication between a web client and a web server over a persistent, single-socket connection. Like HTTP, WebSocket works on top of TCP. Unlike HTTP, WebSockets are stateful. They're suitable for event-driven apps and services that require high-frequency, low-latency communication between client and server. Use cases include live chat, real-time dashboards

REST is a software architectural style - probably the most widespread and commonly used one. Unlike WebSocket, REST is not a protocol, but a set of architectural constraints. A REST API is a middleman for transferring data between a web client and a web server. It uses the HTTP communication protocol and provides a lightweight way for web clients to perform CRUD (Create, Read, Update and Delete) operations via different methods (or HTTP verbs). The most commonly-used methods are GET, PUT, POST, DELETE, and PATCH.

Criteria	WebSocket	REST
Performance	WebSockets have a low overhead per message. They're ideal for use cases that require low-latency, high-frequency communication.	REST APIs have a higher message overhead compared to WebSockets. They're best suited for use cases where you want to create, retrieve, delete, or update resources.
Nature	Socket-based.	Resource-based.
HTTP use	WebSocket uses HTTP only during the initial request/response handshake (connection establishment).	REST uses HTTP to enable client-server communication.
Communication	Event-driven and bidirectional.	Request-driven and unidirectional.
State	WebSocket is a stateful protocol.	REST uses the HTTP protocol, which is stateless.
TCP connection	A WebSocket connection uses a single TCP connection for data exchange.	Every request/response requires a new TCP connection.

120. Difference between Inheritance and Composition in C#?

In inheritance, there is an image of the base class in the derived class object, so the image of the base class is created when the derived class object is created. We use inheritance to achieve an is-a relationship between classes.

Composition allows late creation of the backend class object until and unless they are not really required. We use composition to create a has-a relationship between classes.

121. What is dependency Injection?

A class (B) is said to be dependent on another class (A) if it contains an instance that is hard coded into it, from the other class (A). This can be problematic due to the following:

- To replace class B with a different implementation, the class A class must be modified.
- If class A has dependencies, they must also be configured by the class B. In a large project with multiple classes depending on class A, the configuration code becomes scattered across the app.
- This implementation is difficult to unit test. The app should use a mock or stub class A, which isn't possible with this approach.

Dependency injection addresses these problems through:

- The use of an interface or base class to abstract the dependency implementation.
- Registration of the dependency in a service container. .NET provides a built-in service container, [IServiceProvider](#). Services are typically registered at the app's start-up and appended to an [IServiceCollection](#). Once all services are added, you use [BuildServiceProvider](#) to create the service container.
- *Injection* of the service into the constructor of the class where it's used. The framework takes on the responsibility of creating an instance of the dependency and disposing of it when it's no longer needed.

Sample code:

```
using DependencyInjection.Example;
var builder = Host.CreateDefaultBuilder(args);
builder.ConfigureServices( services => services.AddHostedService<Worker>()
.AddScoped<IMessageWriter, MessageWriter>());
using var host = builder.Build();
host.Run();
```

121. What is SOLID?

SOLID is an acronym, introduced by Michael Feathers, for five design principles used to make software design more understandable, flexible, and maintainable. These principles are a subset of many principles promoted by Robert C. Martin.

SOLID Principles

There are five SOLID principles:

1. Single Responsibility Principle (SRP)

2. Open Closed Principle (OCP)
3. Liskov Substitution Principle (LSP)
4. Interface Segregation Principle (ISP)
5. Dependency Inversion Principle (DIP)

Single Responsibility Principle (SRP)

Definition: A class should have only one reason to change.

In layman terminology, this means that a class should not be loaded with multiple responsibilities and a single responsibility should not be spread across multiple classes or mixed with other responsibilities. The reason is that more changes requested in the future, the more changes the class need to apply.

In simple terms, a module or class should have a very small piece of responsibility in the entire application. Or as it states, a class/module should have not more than one reason to change.

Classes, software components and modules that have only one responsibility are much easier to explain, implement and understand than ones that give a solution for everything. This also reduces number of bugs and improves development speed and most importantly makes developer's life lot easier.

Open Closed Principle (OCP)

Definition: Software entities (classes, modules, functions, etc.) should be open for extension, but closed for modification.

This principle suggests that the class should be easily extended but there is no need to change its core implementations.

The application or software should be flexible to change. How change management is implemented in a system has a significant impact on the success of that application/ software. The OCP states that the behaviors of the system can be extended without having to modify its existing implementation.

Liskov Substitution Principle (LSP)

Definition: Functions that use pointers or references to base classes must be able to use objects of derived classes without knowing it.

LSP states that the child class should be perfectly substitutable for their parent class. If class C is derived from P, then C should be substitutable for P.

LSP is a fundamental principle of SOLID Principles and states that if program or module is using base class then derived class should be able to extend their base class without changing their original implementation.

Interface Segregation Principle (ISP)

Definition: No client should be forced to implement methods which it does not use, and the contracts should be broken down to thin ones.

Interface segregation principle is required to solve the design problem of the application. When all the tasks are done by a single class or in other words, one class is used in almost all the application classes then it has become a fat class with overburden. Inheriting such class will results in having sharing methods which are not relevant to derived classes but its there in the base class so that will inherit in the derived class.

Using ISP, we can create separate interfaces for each operation or requirement rather than having a single class to do the same work.

Dependency Inversion Principle (DIP)

Definition:

1. High-level modules should not depend on low-level modules. Both should depend on abstractions.
2. Abstractions should not depend on details. Details should depend on abstractions.

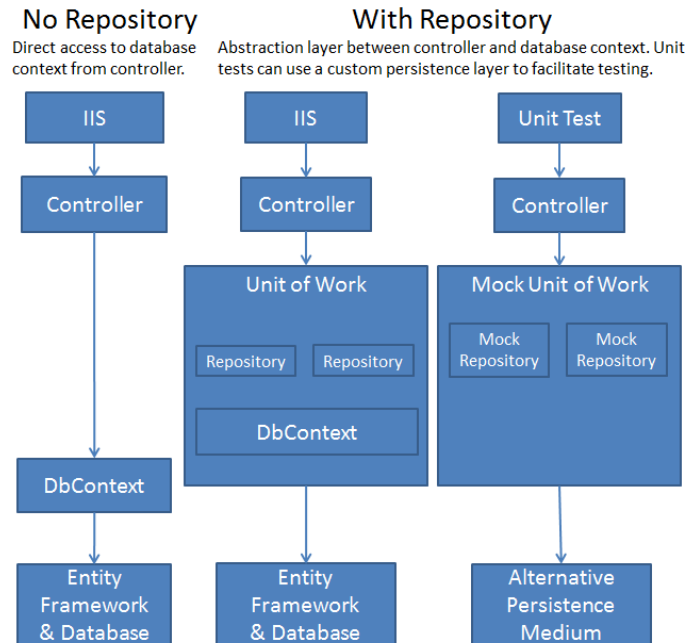

The principle says that high-level modules should depend on abstraction, not on the details, of low-level modules. In simple words, the principle says that there should not be a tight coupling among components of software and to avoid that, the components should depend on abstraction.

The terms Dependency Injection (DI) and Inversion of Control (IoC) are generally used as interchangeably to express the same design pattern. The pattern was initially called IoC, but Martin Fowler (known for designing the enterprise software) anticipated the name as DI because all frameworks or runtime invert the control in some way, and he wanted to know which aspect of control was being inverted.

Inversion of Control (IoC) is a technique to implement the Dependency Inversion Principle in C#. Inversion of control can be implemented using either an abstract class or interface. The rule is that the lower-level entities should join the contract to a single interface and the higher-level entities will use only entities that are implementing the interface. This technique removes the dependency between the entities.

122. What is Unit of Work? How to use it with Repository Pattern?

The repository and unit of work patterns are intended to create an abstraction layer between the data access layer and the business logic layer of an application. Implementing these patterns can help insulate your application from changes in the data store and can facilitate automated unit testing or test-driven development (TDD).

In many applications, the business logic accesses data from data stores such as databases, SharePoint lists, or Web services. Directly accessing the data can result in the following:

- Duplicated code
- A higher potential for programming errors
- Weak typing of the business data
- Difficulty in centralizing data-related policies such as caching
- An inability to easily test the business logic in isolation from external dependencies

Use the Repository pattern to achieve one or more of the following objectives:

- You want to maximize the amount of code that can be tested with automation and to isolate the data layer to support unit testing.
- You access the data source from many locations and want to apply centrally managed, consistent access rules and logic.
- You want to implement and centralize a caching strategy for the data source.
- You want to improve the code's maintainability and readability by separating business logic from data or service access logic.
- You want to use business entities that are strongly typed so that you can identify problems at compile time instead of at run time.
- You want to associate a behavior with the related data. For example, you want to calculate fields or enforce complex relationships or business rules between the data elements within an entity.
- You want to apply a domain model to simplify complex business logic.

Use a repository to separate the logic that retrieves the data and maps it to the entity model from the business logic that acts on the model. The business logic should be agnostic to the type of data that comprises the data source layer. For example, the data source layer can be a database, a SharePoint list, or a Web service.

The repository mediates between the data source layer and the business layers of the application. It queries the data source for the data, maps the data from the data source to a business entity, and persists changes in the business entity to the data source. A repository separates the business logic from the interactions with the underlying data source or Web service. The separation between the data and business tiers has three benefits:

- It centralizes the data logic or Web service access logic.
- It provides a substitution point for the unit tests.
- It provides a flexible architecture that can be adapted as the overall design of the application evolves.

With Unit of Work pattern, you can encapsulate several related operations that should be consistent with each other or that have related dependencies. The encapsulated items are sent to the repository for update or delete actions.

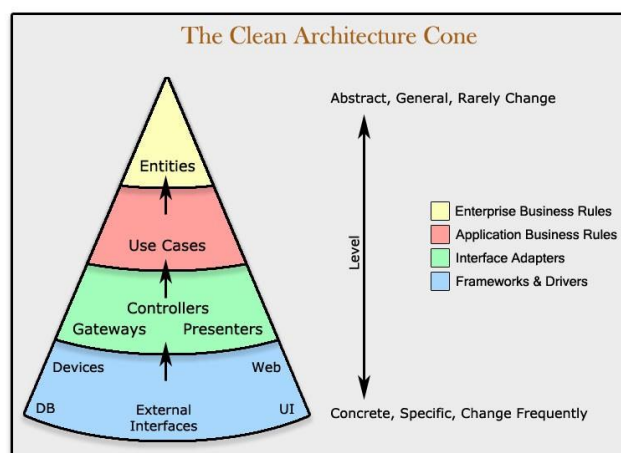

123. What is Clean Architecture?

Applications that follow the Dependency Inversion Principle as well as the Domain-Driven Design (DDD) principles tend to arrive at a similar architecture. This architecture has gone by many names over the years. One of the first names was Hexagonal Architecture, followed by Ports-and-Adapters. More recently, it's been cited as the [Onion Architecture](#) or [Clean Architecture](#)

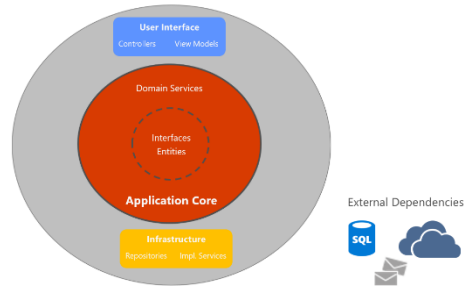

A better example of clean Architecture, found on freecodecamp's website.

Same as above, but in a cone shaped figure for easier visualization.

Clean Architecture Layers (Onion view)

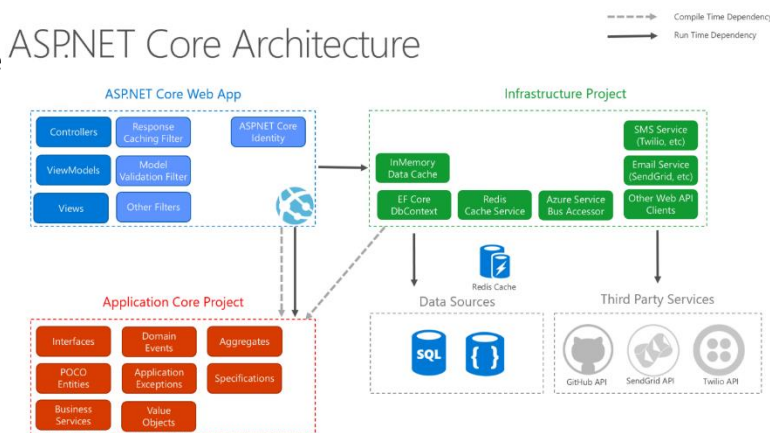

In the above diagram, dependencies flow toward the innermost circle. The Application Core takes its name from its position at the core of this diagram. And you can see on the diagram that the Application Core has no dependencies on other application layers. The application's entities and interfaces are at the very center. Just outside, but still in the Application Core, are domain services, which typically implement interfaces defined in the inner circle. Outside of the Application Core, both the UI and the Infrastructure layers depend on the Application Core, but not on one another (necessarily).

Clean Architecture Layers

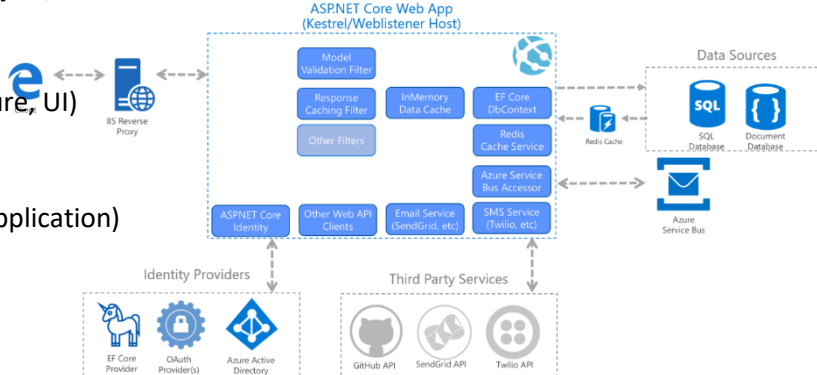

Note that the solid arrows represent compile-time dependencies, while the dashed arrow represents a runtime-only dependency. With the clean architecture, the UI layer works with interfaces defined in the Application Core at compile time, and ideally shouldn't know about the implementation types defined in the Infrastructure layer. At run time, however, these implementation types are required for the app to execute, so they need to be present and wired up to the Application Core interfaces via dependency injection.

More detailed view
Of an ASP.NET Core
Application's
Architecture when
Built following
Clean Architecture.

Example of ASP.NET Core Architecture when all parts of project (Core, Infrastructure, UI) are run as a single application (i.e., Monolithic application)

Organizing code in Clean Architecture

In a Clean Architecture solution, each project has clear responsibilities. As such, certain types belong in each project, and you'll frequently find folders corresponding to these types in the appropriate project.

Application Core

The Application Core holds the business model, which includes entities, services, and interfaces. These interfaces include abstractions for operations that will be performed using Infrastructure, such as data access, file system access, network calls, etc. Sometimes services or interfaces defined at this layer will need to work with non-entity types that have no dependencies on UI or Infrastructure. These can be defined as simple Data Transfer Objects (DTOs).

Application Core types

- Entities (business model classes that are persisted)
- Aggregates (groups of entities)
- Interfaces
- Domain Services
- Specifications
- Custom Exceptions and Guard Clauses
- Domain Events and Handlers

Infrastructure

The infrastructure project typically includes data access implementations. In a typical ASP.NET Core web application, these implementations include the Entity Framework (EF) DbContext, any EF Core Migration objects that have been defined, and data access implementation classes. The most common way to abstract data access implementation code is using the [Repository design pattern](#).

In addition to data access implementations, the infrastructure project should contain implementations of services that must interact with infrastructure concerns. These services should implement interfaces

defined in the Application Core, and so Infrastructure should have a reference to the Application Core project.

Infrastructure types

- EF Core types (DbContext, Migration)
- Data access implementation types (Repositories)
- Infrastructure-specific services (for example, FileLogger or SntpNotifier)

UI Layer

The user interface layer in an ASP.NET Core MVC application is the entry point for the application. This project should reference the Application Core project, and its types should interact with infrastructure strictly through interfaces defined in Application Core. No direct instantiation of or static calls to the Infrastructure layer types should be allowed in the UI layer.

UI Layer types

- Controllers
- Custom Filters
- Custom Middleware
- Views
- ViewModels
- Startup

The Startup class or *Program.cs* file is responsible for configuring the application, and for wiring up implementation types to interfaces. The place where this logic is performed is known as the app's *composition root*, and is what allows dependency injection to work properly at run time.

106. What is Query Execution Plan?

To be able to execute queries, the SQL Server Database Engine must analyze the statement to determine the most efficient way to access the required data. This analysis is handled by a component called the Query Optimizer.

A query execution plan is a definition of the following:

- **The sequence in which the source tables are accessed.**
Typically, there are many sequences in which the database server can access the base tables to build the result set. For example, if a SELECT statement references three tables, the database server could first access TableA, use the data from TableA to extract matching rows from TableB, and then use the data from TableB to extract data from TableC.
- **The methods used to extract data from each table.**
Generally, there are different methods for accessing the data in each table. If only a few rows with specific key values are required, the database server can use an index. If all the rows in the

table are required, the database server can ignore the indexes and perform a table scan. If all the rows in a table are required but there is an index whose key columns are in an ORDER BY, performing an index scan instead of a table scan may save a separate sort of the result set. If a table is very small, table scans may be the most efficient method for almost all access to the table.

- **The methods used to compute calculations, and how to filter, aggregate, and sort data from each table.**

As data is accessed from tables, there are different methods to perform calculations over data such as computing scalar values, and to aggregate and sort data as defined in the query text, for example when using a GROUP BY or ORDER BY clause, and how to filter data, for example when using a WHERE or HAVING clause.

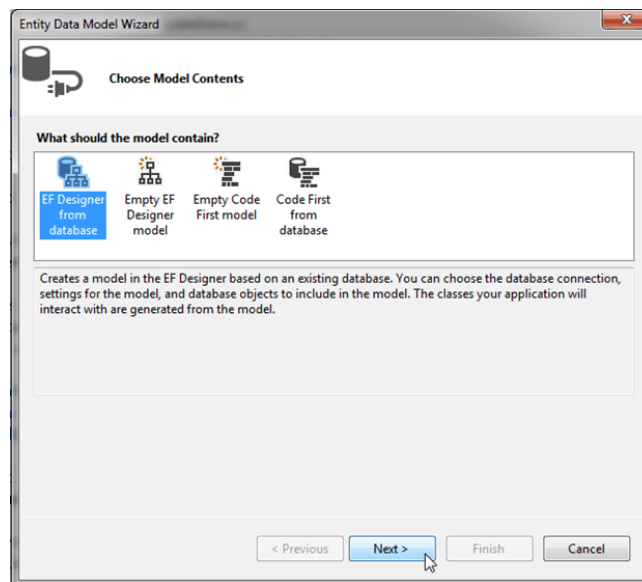

124. What is SQL Server Profiler?

SQL Server Profiler is an interface to create and manage traces and analyze and replay trace results. Events are saved in a trace file that can later be analyzed or used to replay a specific series of steps when diagnosing a problem. You can start the Profiler within **SQL Server Management Studio** or with the **Azure Data Studio** using the SQL Server Profiler extension.

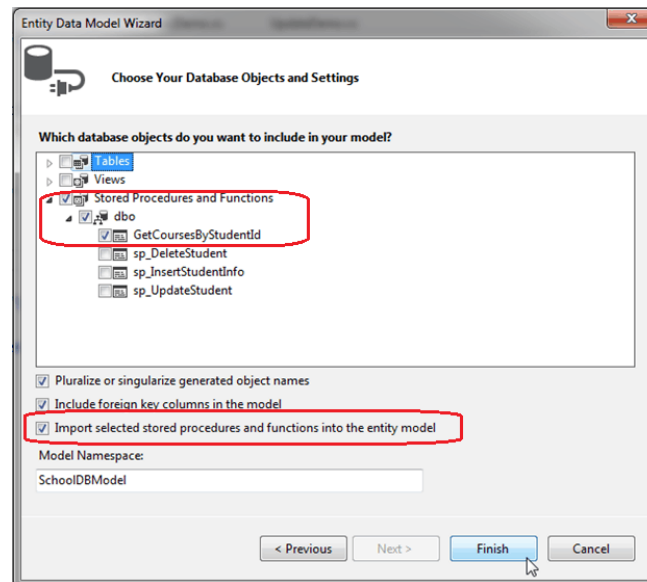

125. How to call Stored Procedures from Entity Framework Core?

EF API creates a function instead of an entity in EDM for each stored procedure and User-Defined Function (UDF) in the target database.

Now, add a new Entity Data Model by right clicking on the project in the solution explorer in Visual Studio (2012/2015/2017) -> Add -> New Item. This will open an Add New Item popup. In the popup, select ADO.NET Entity Data Model and provide an appropriate name for the EDM and click the Add button. This will open Entity Data Model Wizard. Select EF Designer from database and click the Next button.

Connect to your server and open test connection with Database, and then select the target **Stored Procedures & Functions**. Make sure that the **Import selected stored procedures and functions into the entity model** checkbox is selected and then click Finish.

Or, EF Core provides the following methods to **execute a stored procedure directly as SQL script**:

- `DbSet<TEntity>.FromSql()`
- `DbContext.Database.ExecuteSqlCommand()`

There are some limitations on the execution of database stored procedures using `FromSql` or `ExecuteSqlCommand` methods in EF Core2:

- Result must be an entity type. This means that a stored procedure must return all the columns of the corresponding table of an entity.
- Result cannot contain related data. This means that a stored procedure cannot perform JOINS to formulate the result.
- Insert, Update and Delete procedures cannot be mapped with the entity, so the `SaveChanges` method cannot call stored procedures for CUD operations.

Example:

```
var context = new SchoolContext();
var param = new SqlParameter("@FirstName", "Bill");
var students = context.Students.FromSql("GetStudents @FirstName",
param).ToList();
```

Or:

```
var context = new SchoolContext();
var students = context.Students.FromSql("GetStudents @p0", "Bill").ToList();
```

Another Example:

```
var context = new SchoolContext();
context.Database.ExecuteSqlCommand("CreateStudents @p0, @p1", parameters:
new[] { "Bill", "Gates" });
```

126. After applying a specific migration, how to un-apply a migration?

- To un-apply a specific migration(s):
PM> Update-Database -Migration LastGoodMigrationName
- To un-apply all migrations:
PM> Update-Database -Migration 0

Note: You can also remove migration with PM> Remove-Migration, this removes last migration.

Note: To un-apply and remove last migration: PM> Remove-Migration -Force (PM is Package Manager).

127. What is CTE in Transact-SQL? (Common Table Expression)

A Common Table Expression, also called as CTE in short form, is a temporary named result set that you can reference within a SELECT, INSERT, UPDATE, or DELETE statement. The CTE can also be used in a View. A common table expression can include references to itself. This is referred to as a recursive common table expression

Example:

```
with ROWCTE(ROWNO) as
(
    SELECT
        ROW_NUMBER() OVER(ORDER BY name ASC) AS ROWNO
    FROM sys.databases
    WHERE database_id <= 10
)
SELECT * FROM ROWCTE
```

128. What is temp tables?

As its name indicates, temporary tables are used to store data temporarily and they can perform CRUD (Create, Read, Update, and Delete), join, and some other operations like the persistent database tables. Temporary tables are dropped when the session that creates the table has closed or can also be explicitly dropped by users. At the same time, temporary tables can act like physical tables in many ways, which gives us more flexibility. Such as, we can create constraints, indexes, or statistics in these tables. There is two types: **Local Temp Tables**, and **Global Temp Tables**.

Local Temp Tables:

The accessible scope of local temporary tables is limited by the connection in which they were created. In other words, the local temporary tables are visible for the duration of the connection and when the session is closed the local temporary table are dropped automatically. Local temporary tables can be created using the "CREATE TABLE" syntax but a single hashtag (#) sign must be added in front of their names. The following example script will create a new **local temporary table** named TempPersonTable.

```
CREATE TABLE #TempPersonTable (
    PersonID int PRIMARY KEY IDENTITY(1,1),
    LastName varchar(255),
    FirstName varchar(255),
    City varchar(255)
)
```

When we query the TempPersonTable, it will return an empty result set.

```
SELECT * FROM #TempPersonTable
```

At the same time, we can create a temporary table using the SQL SELECT INTO statement command. The following query will create a local temporary copy of the Orders table.

```
SELECT * INTO #TempOrdersTable
FROM Orders
SELECT * FROM #TempOrdersTable
```

The local temporary tables are created in the tempdb database with a unique name because they can be created with the same name by the other connections.

Global Temp Tables:

The global temporary tables are created using the CREATE TABLE statement and their names must be prefixed with the double hashtag (##) sign. These tables can be accessed by all other sessions, unlike local ones. The following code will create a global temporary table.

```
CREATE TABLE ##Customers (CustomerId INT IDENTIT
Y(1,1) PRIMARY KEY,
CustomerFullName VARCHAR(50),
EMail VARCHAR(50),
CustomerAddress VARCHAR(50),
Country VARCHAR(50))
```

After creating the temporary table, we can populate and query it.

```
INSERT INTO ##Customers
VALUES('Olivia Rodriguez','hldw.wvmqi@rkx.co','66 Eli
zabeth Street','Canada'),
('Riley Hall','efkfu.ngtpgi@rgg.org','23 Brookside Drive','
U.K. '),
('Allison Lopez','ygpnm.wdvyufu@bevl.com','11 Church
Road','South Africa'),
('Gianna King','nklwjv.wimmhxr@ncni.co','193 Park Plac
e','Belgium')
SELECT * FROM ##Customers
```

Global table names are not transformed into a unique name.

Global temporary tables can be dropped explicitly with the DROP TABLE statement on any connection or automatically dropped when the session is closed that creates the table. However, this global table should not be actively in use by the other sessions. If it is actively in use by the other sessions, SQL Server waits until the completion of the last SQL statement activities that use the global temporary table, and then the global table is dropped.

Note: On the other hand, **in-memory optimized tables** have been entered our data life with **SQL Server 2014**, and schema only optimized tables can store the data until the database restart. In this context, the temp tables and schema only memory-optimized tables have similar functionalities in terms of storing data temporarily. The main advantage of using the memory-optimized tables instead of the temporary tables is to remove I/O activities so it has more performance, but we have to notice that they consume memory.

129. Tracking vs NoTracking in EntityFrameworkCore?

- Tracking:

By default, queries that return entity types are tracking. Which means you can make changes to those entity instances and have those changes persisted by SaveChanges(). In the following example, the change to the blogs rating will be detected and persisted to the database during SaveChanges().

```
var blog = context.Blogs.SingleOrDefault(b => b.BlogId == 1);
blog.Rating = 5;
context.SaveChanges();
```

- **No Tracking:**
No tracking queries are useful when the results are used in a read-only scenario. They're quicker to execute because there's no need to set up the change tracking information. If you don't need to update the entities retrieved from the database, then a no-tracking query should be used. You can swap an individual query to be no-tracking. No tracking query will also give you results based on what is in the database disregarding any local changes or added entities.

```
var blogs = context.Blogs
    .AsNoTracking()
    .ToList();
```

You can also change this behavior on the context level.

```
context.ChangeTracker.QueryTrackingBehavior =
    QueryTrackingBehavior.NoTracking;
var blogs = context.Blogs.ToList();
```

130. What is the difference between IEnumerable & IQueryable?

IQueryable inherits IEnumerable, also IEnumerable is good for in memory usage, while IQueryable is better for remote data (in a database, etc..). IEnumerable doesn't support lazy loading which means it is not good for paging (eager loading), while IQueryable does. IQueryable supports custom query using CreateQuery and Execute methods whereas IEnumerable does not.

131. How to use Database First approach in EntityFramework Core?

EF Core does not support visual designer for DB model and wizard to create the entity and context classes similar to EF 6. So, we need to do reverse engineering using the Scaffold-DbContext command. This reverse engineering command creates entity and context classes (by deriving DbContext) based on the schema of the existing database.

Use **Scaffold-DbContext** to create a model based on your existing database. The following parameters can be specified with Scaffold-DbContext in Package Manager Console:

```
Scaffold-DbContext [-Connection] [-Provider] [-OutputDir] [-Context] [-Schemas>]
[-Tables>]
                    [-DataAnnotations] [-Force] [-Project] [-StartupProject]
[<CommonParameters>]
```

In Visual Studio, select menu Tools -> NuGet Package Manger -> Package Manger Console and run the following command:

```
PM>Scaffold-DbContext
    "Server=.\SQLEXPRESS;Database=SchoolDB;Trusted_Connection=True;"
    Microsoft.EntityFrameworkCore.SqlServer -OutputDir Models
```

132. What are the types of Row deletion in EntityFramework Core?

- **Cascade:** For entities being tracked by the context, dependent entities will be deleted when the related principal is deleted.
- **ClientSetNull:** It is the default value. Here foreign key is set to null.
- **Restrict:** Prevents delete. (Cannot delete if there are foreign key references.)
- **SetNull:** The foreign key values in dependent rows should update to NULL.
Note: If using PostgreSQL, there are differences!

133. What does JWT consist of? How to use it in authentication? (ASP.NET Core Token Authentication)

- **Header**

The header typically consists of two parts: the type of the token, which is JWT, and the algorithm that is used, such as HMAC SHA256 or RSA SHA256. It is Base64Url encoded to form the first part of the JWT.

- **Payload**

The payload contains the claims. There is a set of registered claims, for example: iss (issuer), exp (expiration time), sub (subject), and aud (audience). These claims are not mandatory but recommended to provide a set of useful, interoperable claims. The payload can also include extra attributes that define custom claims, such as employee role. Typically, the subject claim is used to create the OpenID Connect user subject. However, the Liberty JVM server can be configured to use an alternative claim. The payload is Base64Url encoded to form the second part of the JWT.

- **Signature**

To create the signature part, the encoded header and encoded payload are signed by using the signature algorithm from the header. The signature is used to verify that the issuer of the JWT is who it says it is and to ensure that the message wasn't changed along the way.

Now in the ASP.NET Core project, we install these 2 libraries from Nuget:

Microsoft.AspNetCore.Authentication.JwtBearer and System.IdentityModel.Tokens.Jwt.

Our appsetting.json file looks similar to as written below:

```
{
  "Logging": {
    "LogLevel": {
      "Default": "Information",
      "Microsoft": "Warning",
      "Microsoft.Hosting.Lifetime": "Information"
    }
  },
  "AllowedHosts": "*",
  "JWT": {
    "Key": "This is my supper secret key for jwt",
    "Issuer": "https://codepedia.info",
    "Audience": "codepedia.info"
  }
}
```

Our Startup.cs file code look like as written below:

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddAuthentication(x =>
    {
        x.DefaultAuthenticateScheme = JwtBearerDefaults.AuthenticationScheme;
        x.DefaultChallengeScheme = JwtBearerDefaults.AuthenticationScheme;
    }).AddJwtBearer(o =>
    {
        var Key = Encoding.UTF8.GetBytes(Configuration["JWT:Key"]);
        o.SaveToken = true;
        o.TokenValidationParameters = new TokenValidationParameters
        {
            ValidateIssuer = false,
            ValidateAudience = false,
            ValidateLifetime = true,
            ValidateIssuerSigningKey = true,
            ValidIssuer = Configuration["JWT:Issuer"],
            ValidAudience = Configuration["JWT:Audience"],
            IssuerSigningKey = new SymmetricSecurityKey(Key)
        };
    });

    services.AddSingleton<JWTManagerRepository, JWTManagerRepository>();

    services.AddControllers();
}
```

Don't forget to add `UseAuthentication()` and `UseAuthorization()` in the middleware. Then:

Users.cs file code:

```
public class Users
{
    public string Name { get; set; }
    public string Password { get; set; }
}
```

Tokens.cs file code:

```
public class Tokens
{
    public string Token { get; set; }
    public string RefreshToken { get; set; }
}
```

Create an `IJWTManagerRepository` interface to Authenticate users and generate JSON Web Token.

```
using JWTWebAuthentication.Models;
using System;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;

namespace JWTWebAuthentication.Repository
{
    public interface IJWTManagerRepository
    {
        Tokens Authenticate(Users users);
    }
}
```

```
public class JWTManagerRepository : IJWTManagerRepository
{
    Dictionary<string, string> UsersRecords = new Dictionary<string, string>
    {
        { "user1", "password1"},
        { "user2", "password2"},
        { "user3", "password3"},
    };

    private readonly IConfiguration iconfiguration;
    public JWTManagerRepository(IConfiguration iconfiguration)
    {
        this.iconfiguration = iconfiguration;
    }

    public Tokens Authenticate(Users users)
    {
        if (!UsersRecords.Any(x => x.Key == users.Name && x.Value == users.Password)) {
            return null;
        }

        // Else we generate JSON Web Token
        var tokenHandler = new JwtSecurityTokenHandler();
        var tokenKey = Encoding.UTF8.GetBytes(iconfiguration["JWT:Key"]);
        var tokenDescriptor = new SecurityTokenDescriptor
        {
            Subject = new ClaimsIdentity(new Claim[]
            {
                new Claim(ClaimTypes.Name, users.Name)
            }),
            Expires = DateTime.UtcNow.AddMinutes(10),
            SigningCredentials = new SigningCredentials(new SymmetricSecurityKey(tokenKey), SecurityAlgorithms.HmacSha256Signature)
        };
        var token = tokenHandler.CreateToken(tokenDescriptor);
        return new Tokens { Token = tokenHandler.WriteToken(token) };
    }
}
```

Create UserController - Authenticate action method

```
[Authorize]
[Route("api/[controller]")]
[ApiController]
public class UsersController : ControllerBase
{
    private readonly IJWTManagerRepository _jWTManager;

    public UsersController(IJWTManagerRepository jwtManager)
    {
        this._jWTManager = jwtManager;
    }

    [HttpGet]
    public List<string> Get()
    {
        var users = new List<string>
        {
            "Satinder Singh",
            "Amit Sarna",
            "Davin Jon"
        };

        return users;
    }
}

[AllowAnonymous]
[HttpPost]
[Route("authenticate")]
public IActionResult Authenticate(Users usersdata)
{
    var token = _jWTManager.Authenticate(usersdata);

    if (token == null)
    {
        return Unauthorized();
    }

    return Ok(token);
}
}
```

134. Why do we use MSMQ?

Microsoft Message Queuing, or MSMQ, is technology for asynchronous messaging. Whenever there's need for two or more applications (processes) to send messages to each other without having to immediately know results, MSMQ can be used. MSMQ can communicate between remote machines, even over Internet. It's free and comes with Windows but is not installed by default.

This mainly addresses the common use case of asynchronous message processing: you have a service Service1 that communicates (send messages) with another part of your software architecture, say Service2.

135. Define what is let clause?

In a query expression, it is sometimes useful to store the result of a sub-expression to use it in subsequent clauses. You can do this with the `let` keyword, which creates a new range variable and initializes it with the result of the expression you supply.

```
var names = new string[] { "Dog", "Cat", "Giraffe", "Monkey", "Tortoise" };
var result =
    from animalName in names
    let nameLength = animalName.Length
    where nameLength > 3
    orderby nameLength
    select animalName;
```

136. Explain the difference between Task and Thread in .NET?

- **Thread** represents an actual OS-level thread, with its own stack and kernel resources. Thread allows the highest degree of control; you can `Abort()` or `Suspend()` or `Resume()` a thread, you can observe its state, and you can set thread-level properties like the stack size, apartment state, or culture. `ThreadPool` is a wrapper around a pool of threads maintained by the CLR.
- The **Task class** from the Task Parallel Library offers the best of both worlds. Like the `ThreadPool`, a task does not create its own OS thread. Instead, tasks are executed by a `TaskScheduler`; the default scheduler simply runs on the `ThreadPool`. Unlike the `ThreadPool`, `Task` also allows you to find out when it finishes, and (via the generic `Task`) to return a result.

137. What is lambda expressions in C#?

A **lambda expression** is an anonymous function that you can use to create delegates or *expression tree* types. By using lambda expressions, you can write local functions that can be passed as arguments or returned as the value of function calls. Lambda expressions are particularly helpful for writing LINQ query expressions.

138. Name some advantages of LINQ over Stored Procedures.

1. **Debugging** - It is really very hard to debug the Stored procedure but as LINQ is part of .NET, you can use visual studio's debugger to debug the queries.
2. **Deployment** - With stored procedures, we need to provide an additional script for stored procedures but with LINQ everything gets compiled into single DLL hence deployment becomes easy.
3. **Type Safety** - LINQ is type safe, so queries errors are type checked at compile time. It is good to encounter an error when compiling rather than runtime exception!
4. **Built-in security** - One reason to prefer stored procedures before LINQ was that they forced the use of parameters, helping to reduce SQL injection attacks. LINQ to SQL already parameterizes input, which is just as secure.

5. **Reduction in work** - Before LINQ, you would spend a lot of time building DALs, but now DataContext is the DAL. You could use OPFs too, but now you have LINQ that ships with multiple providers in the box and many other 3rd party providers, giving the benefits from previous points.
6. **Abstraction**: This is especially true with [LINQ-to-Entities](#). This abstraction also allows the framework to add additional improvements that you can easily take advantage of. [PLINQ](#) is an example of adding multi-threading support to LINQ. Code changes are minimal to add this support. It would be MUCH harder to do this data access code that simply calls stored procedures.
7. **Debugging support**: You can use any .NET debugger to debug the queries. With stored procedures, you cannot easily debug the SQL and that experience is largely tied to your database vendor (MS SQL Server provides a query analyzer, but often that isn't enough).
8. **Vendor agnostic**: LINQ works with lots of databases and the number of supported databases will only increase. stored procedures are not always portable between databases, either because of varying syntax or feature support (if the database supports stored procedures at all).
9. **Easier**: You don't have to learn T-SQL to do data access, nor do you have to learn the data access API (e.g., ADO.NET) necessary for calling the stored procedures. This is related to #3 and #4.

139. What is GOD class and why should we avoid it?

A God class is usually a huge class that concentrates a lot of responsibilities, controls and oversees many different objects, and effectively does everything in the application.

SOLID is an acronym, and the S stands for the **single-responsibility principle**, which broadly means that each module/class/function should strive to do a single thing. **God** classes are the literal opposite of the single-responsibility principle, taking on too many responsibilities and being highly unfocused. This causes engineers to reinvent the wheel, duplicate code, and incur technical debt.

140. What is Indexer in C#?

Indexers allow instances of a class or struct to be indexed just like arrays. The indexed value can be set or retrieved without explicitly specifying a type or instance member. Indexers resemble properties except that their accessors take parameters.

141. What is the yield keyword used for in C#?

Yield keyword helps to do custom stateful iteration over a collection. Meaning when we use yield keyword the control moves back and forth from the caller function to source and vice versa.

If the function returns an object that implements the IEnumerable<object> interface, and a calling function starts "foreach"ing over this object, the function is called again until it "yields". This is syntactic sugar introduced in C# 2.0. In earlier versions you had to create your own IEnumerable and IEnumerator objects to do stuff like this. (More like a state machine under-the-hood.)

142. When would you use Duplex WCF service?

You need duplex if you want to implement callback pattern. Callback means that client does not know when some event happens in server.

If you do not know when event happens you have two options to implement:

1. Polling - send requests every X minutes to check if event happened. Server should either return event details (if it happened) or return flag saying that you need to continue calling. Server also can return recommended timeout in advanced scenarios.

2. Callback - client sends some form of description what server should do if event happened. This may be pointer to function in C, delegate in .NET or endpoint schema in WCF. Server remembers that info and makes call from their side when time came.

As you can see duplex/callback means that at some point server works as client (initiates communication) and this is a big game change.

WCF duplex communications may require special network configuration because in many cases network allows you to call external services (you work as client) but forbids external resources to call you (external service works as client). This is implemented for security purposes.

143. What is difference between WCF and Web API and WCF REST and Web Service?

Web Service

1. It is based on SOAP and return data in XML form.
2. It support only HTTP protocol.
3. It is not open source but can be consumed by any client that understands xml.
4. It can be hosted only on IIS.

WCF

1. It is also based on SOAP and return data in XML form.
2. It is the evolution of the web service(ASMX) and support various protocols like TCP, HTTP, HTTPS, Named Pipes, MSMQ. The main issue with WCF is, its tedious and extensive configuration.
3. It is not open source but can be consumed by any client that understands xml.
4. It can be hosted with in the applicaion or on IIS or using window service.

WCF Rest

1. To use WCF as WCF Rest service you have to enable webHttpBindings.
2. It support HTTP GET and POST verbs by [WebGet] and [WebInvoke] attributes respectively.
3. To enable other HTTP verbs you have to do some configuration in IIS to accept request of that particular verb on .svc files
4. Passing data through parameters using a WebGet needs configuration. The UriTemplate must be specified
5. It support XML, JSON and ATOM data format.

Web API

1. This is the new framework for building HTTP services with easy and simple way.
2. Web API is open source an ideal platform for building REST-ful services over the .NET Framework.
3. Unlike WCF Rest service, it use the full feautres of HTTP (like URIs, request/response headers, caching, versioning, various content formats)
4. It also supports the MVC features such as routing, controllers, action results, filter, model binders, IOC container or dependency injection, unit testing that makes it more simple and robust.
5. It can be hosted with in the application or on IIS.
6. It is light weight architecture and good for devices which have limited bandwidth like smart phones.
7. Responses are formatted by Web API's MediaTypeFormatter into JSON, XML or whatever format you want to add as a MediaTypeFormatter.

144. Define use cases for reflection?

Invoking a public/private method, Accessing a private field.

145. Define a use case for dynamic?

The dynamic keyword is new to C# 4.0 and is used to tell the compiler that a variable's type can change or that it is not known until runtime. Think of it as being able to interact with an Object without having to cast it.

146. Are Lambda expressions in C# closures?

A lambda may be implemented using a closure, but it is not itself necessarily a closure. A closure is "a function together with a referencing environment for the non-local variables of that function." If the lambda expression created does not reference any out-of-scope variables, then no closures involved.

147. Explain how anonymous classes instantiated in .NET. Can they be passed as function params?

Anonymous types can be referred to "T" in C# or any letter between a class identifier, <T> for example. You can pass them to a function like: myFunc(T someObj1, U someObj2,)

148. Do you think it's possible in .NET to extend a class (any class) with some extra methods? If yes, how can it be accomplished?

Yes, using **extension methods**!

```
namespace ExtensionMethods
{
    public static class MyExtensionMethods
    {
        public static DateTime Tomorrow(this DateTime date)
        {
            return date.AddDays(1);
        }
    }
}
```

Usage:

```
DateTime.Now.Tomorrow();
```

149. What are the key differences between the preemptive threading model and the cooperative threading model?

In cooperative models, once a thread is given control it continues to run until it explicitly yields control or it blocks. In a preemptive model, the virtual machine is allowed to step in and hand control from one thread to another at any time.

150. How would you accomplish lazy initialization in .NET?

The System.Lazy<T> class simplifies the work of performing lazy initialization and instantiation of objects. By initializing objects in a lazy manner, you can avoid having to create them at all if they are never needed, or you can postpone their initialization until they are first accessed.

151. In what case would you mark a field as volatile?

The volatile keyword indicates that a field might be modified by multiple threads that are executing at the same time. The compiler, the runtime system, and even hardware may rearrange reads and writes to memory locations for performance reasons. Fields that are declared volatile are excluded from certain kinds of optimizations. There is no guarantee of a single total ordering of volatile writes as seen from all threads of execution.

152. Differentiate between Unit-Testing and Functional-Testing?

Unit testing involves isolating the smallest testable parts of an application into units that you can verify and validate independently. It is a key step in the software development process.

Unit testing helps isolate specific code and determine if the unit works as intended. The goal is to facilitate early detection of code flaws that may be difficult to find and fix in later testing stages.

Functional testing helps verify that each application feature works as intended. It involves comparing each function to the relevant requirement to determine whether the output is consistent with end-user expectations.

You can implement functional testing by providing sample inputs. Next, you capture the resulting outputs and verify that the actual outputs are the same as the expected outputs.

Functional tests employ a black box testing approach that checks functionality without prior knowledge of the internal workings of the software, such as programming languages or software design.

153. What is the difference between Design Principles & Design Patterns?

Design principles provide high level guidelines to design better software applications. They do not provide implementation guidelines and are not bound to any programming language. The SOLID (SRP, OCP, LSP, ISP, DIP) principles are one of the most popular sets of design principles.

On the other hand, Design Pattern provides low-level solutions related to implementation, of commonly occurring object-oriented problems. In other words, design pattern suggests a specific implementation for the specific object-oriented programming problem. For example, if you want to create a class that can only have one object at a time, then you can use the Singleton design pattern which suggests the best way to create a class that can only have one object.

Extra notes:

154. What is NoSQL Databases?

NoSQL databases (aka "not only SQL") are non-tabular databases and store data differently than relational tables. NoSQL databases come in a variety of types based on their data model. The main types are document, key-value, wide-column, and graph. They provide flexible schemas and scale easily with large amounts of data and high user loads.

When people use the term "NoSQL database," they typically use it to refer to any non-relational database. Some say the term "NoSQL" stands for "non SQL" while others say it stands for "not only SQL." Either way, most agree that NoSQL databases are databases that store data in a format other than relational tables.

NoSQL databases emerged in the late 2000s as the cost of storage dramatically decreased. Gone were the days of needing to create a complex, difficult-to-manage data model in order to avoid data duplication. Developers (rather than storage) were becoming the primary cost of software development, so NoSQL databases optimized for developer productivity.

155. What is MongoDB?

MongoDB is a document database with the scalability and flexibility that you want with the querying and indexing that you need.

MongoDB stores data in flexible, JSON-like documents (BSON), meaning fields can vary from document to document and data structure can be changed over time.

Ad hoc queries, indexing, and real time aggregation provide powerful ways to access and analyze your data.

MongoDB is a distributed database at its core, so high availability, horizontal scaling, and geographic distribution are built in and easy, and free to use.

MongoDB (NoSQL Database)	RDBMS (SQL Server, Oracle, etc.)
Database	Database
Collection	Table
Document	Row (Record)
Field	Column

156. What are the advantages of using MongoDB?

- Any type of data can be stored in MongoDB, which gives users the flexibility to create as many fields in a document as they desire.
- Documents map to native data types in many programming languages, which provides a means of adding to data. Sharding, which involves dividing data across a cluster of machines, is also achieved by this.
- MongoDB includes its own file system, similar to the Hadoop Distributed File System (HDFS), called GridFS. The file system is primarily used to store files that exceed MongoDB's 16 MB per document BSON size limit.
- MongoDB is also compatible with Spark, Hadoop, and other data processing frameworks like SQL.

157. What are the disadvantages of using MongoDB?

- When a MongoDB master node goes down, another node will automatically become the new master. Even though it promises continuity, the automatic failover strategy is not instantaneous - it may take up to a minute. In contrast, the Cassandra NoSQL database supports multiple master nodes, so that if a master goes down, another one is ready to run a highly available database infrastructure.
- Although MongoDB's single master node restricts how fast data can be written to the database, it also limits how much data can be written. Because of this, data writes must be recorded on the master, and new information cannot be added to the database quickly.
- MongoDB doesn't provide full referential integrity using foreign-key constraints, which could affect data consistency.
- User authentication isn't enabled by default in MongoDB databases. Because of this, there is a default setting that blocks networked connections to databases if they've not been configured by a database administrator.

- There have also been instances of ransomware attacks that forced the setting to be turned on by the database administrator.

158. What are the features of MongoDB?

1- Replication: The MongoDB replica set feature is known for providing high availability. Two or more copies of data constitute a replica set. A replica-set acts as a primary or a secondary replica. Secondary replicas keep a copy of the data of the primary, preserving it in an orderly manner, as part of a replicated MongoDB system. Whenever a primary replica crashes, the replica set automatically determines which secondary should become the primary and conducts an election if necessary. Secondary replicas may additionally serve read operations, but the data is only eventually consistent by default. To resolve the election of the new primary, three standalone servers must be added as secondary servers.

2- Indexing: A MongoDB field can be indexed with primary and secondary indices or indexes. A MongoDB index stores a small portion of the data set in a form that is convenient to traverse. The index stores the value of a particular field, or set of fields, ordered by their value. In MongoDB, indexes assist in efficiently resolving queries by storing a small portion of the data set in a convenient form. A MongoDB index is similar to a typical relational database index.

3- File storage: GridFS, which uses MongoDB as a file system, can be used to balance and replicate data across multiple machines. A file can be stored in MongoDB as a grid file system. It has features similar to a file system such as load balancing and data replication.

4- Aggregation: The aggregation pipeline, the map-reduce function, and single-purpose aggregation methods are available in MongoDB. According to MongoDB's documentation, the Aggregation Pipeline provides better performance for most aggregation operations over map-reduce. With the aggregation framework, users can obtain the kind of results for which the SQL GROUP BY clause is used. The aggregation framework includes \$lookup and standard deviation like statistical operators.

5- Sharding: Sharding is the splitting up of data among machines. To permit this, we refer to it as "partitioning" or "sharding." We may store more data and handle more load without upgrading our machines, by dividing data across them. MongoDB's sharding allows you to split up a collection among many machines (shards), allowing it to grow beyond resource limitations.

159. Most common mongodb Commands?

1- To show all databases

```
show dbs
```

2- To show current database

```
db
```

3- Switch or create database

```
use acme
```

4. Drop a database

```
db.dropDatabase()
```

5. Inserting Document

```
db.docx.insert({name:'Enterprise',operator:'Star',type:'Explorer',class:'Universe',crew:730,codes:[15,16,17]})
db.docx.insert({name:'Prometheus',operator:'Star',class:'Prometheus',crew:40,codes:[10,14,17]})
```

6. Insert Row

The MongoDB shell provides the following methods to insert rows:

```
db.docx.insert({
  title: 'Post Five',
  body: 'Body of post five',
  category: 'Information',
  tags: ['Information', 'events'],
  user: {
    name: 'David',
    status: 'author'
  },
  date: Date()
})
```

7. Insert Multiple Row

The MongoDB shell provides the following methods to insert multiple rows:

```
db.docx.insertMany([
{
  title: 'Post six',
  body: 'Body of post six',
  category: 'Science',
  date: Date()
},
{
  title: 'Post seven',
  body: 'Body of post seven',
  category: 'Information',
  date: Date()
},
{
  title: 'Post eight',
  body: 'Body of post eight',
  category: 'Sports',
  date: Date()
}
])
```

8. Finding document

The MongoDB shell provides the following methods to find documents:

S. No.	Commands	Description
1.	<code>db.docx.findOne()</code>	Finds one random document.
2.	<code>db.docx.find().prettyPrint()</code>	Finds all documents.

S. No.	Commands	Description
3.	<code>db.docx.find({}, {name:true, _id:false})</code>	Displays only the names of the document Docx.
4.	<code>db.docx.find({}, {name:true, _id:false})</code>	Can find one document by attribute among many documents.

9. Finding Documents using Operators

The MongoDB shell provides the following methods to find documents using operators:

Operator	Description	Commands
\$gt	greater than	<code>db.docx.find({class:{\$gt:'T'}}</code>
\$gte	greater than equals	<code>db.docx.find({class:{\$gt:'T'}}</code>
\$lt	lesser than	<code>db.docx.find({class:{\$lt:'T'}}</code>
\$lte	lesser than equals	<code>db.docx.find({class:{\$lte:'T'}}</code>
\$exists	does an attribute exist or not	<code>db.docx.find({class:{\$gt:'T'}}</code>
\$regex	Matching pattern in pearl-style	<code>db.docx.find({name:{\$regex:'^USS\\sE'}})</code>
\$type	search by type of an element	<code>db.docx.find({name : {\$type:4}})</code>

10. Find one row

To find a row, use-

```
db.docx.findOne({ category: 'Science' })
```

11. Delete a document

deleteOne and deleteMany can be used for this purpose. Both of these methods take a filter document as their first parameter.

```
db.docx.deleteOne({"_id" : 6})
```

12. Delete row

To delete a row, use:

```
db.docx.remove({ title: 'Post six' })
```

13. Sort rows

The MongoDB shell provides the following methods to sort rows:

```
# asc
db.docx.find().sort({ title: 5 }).pretty()
# desc
db.docx.find().sort({ title: -5}).pretty()
```

14. Count Rows

To count number of rows, use:

```
db.docx.find().count()
```

15. Limit rows

To limit the number of rows, use:

```
db.docx.find().limit(5).pretty()
```

16. Update one document

A document stored in the database can be changed using one of several update methods: `updateOne`, `updateMany`, and `replaceOne`.

`updateOne` and `updateMany` take a filter document as their first parameter and a modifier document, which describes changes to make, as the second parameter.

Command: `db.docx.updateOne({"_id": 2}, {$set: {"title": 'revised title'}})`

17. Update Multiple Document

To update multiple documents, use:

`db.docx.update({"category": "Information"}, {$set: {"category": 'Sports'}})`

18. Update Row

The MongoDB shell provides the following method to update row:

```
db.docx.update({ title: 'Post three' },
{
  title: 'Post three,
  body: 'New body for post 3',
  date: Date()
},
{
  upsert: true
})
```

19. Indexes

- **List Indexes:** It can be done by using: `db.docx.getIndexes()`
- **Create Index**

```
db.docx.createIndex({"name": 2})           // single field index
db.docx.createIndex({"name": 2, "date": 2}) // compound index
db.docx.createIndex({foo: "text", bar: "text"}) // text index
db.docx.createIndex({"$*": "text"})        // wildcard text index
db.docx.createIndex({"userMetadata.$*": 1}) // wildcard index
```

- **Drop Index:** `db.docx.dropIndex("name_3")`
- **Hide/Unhide Indexes**
 - To Hide: `db.docx.hideIndex("name_3")`
 - To Unhide: `db.docx.unhideIndex("name_3")`
- **Creating a compound index:** `db.docx.ensureIndex({name : 3, operator : 1, class : 0})`
- **Dropping a compound index:** `db.docx.dropIndex({name : 3, operator : 1, class : 0})`

20. Aggregation

Operator	Description	Command
\$sum	Sum up values	db.docx.aggregate([{\$group : {_id : "\$operator", num_docx : {\$sum : "\$value"}}}])
\$avg	Calculates average values	db.docx.aggregate([{\$group : {_id : "\$operator", num_docx : {\$avg : "\$value"}}}])
\$min / \$max	Find min/max values	db.docx.aggregate([{\$group : {_id : "\$operator", num_docx : {\$min : "\$value"}}}])
\$push	Push values to a result array	db.docx.aggregate([{\$group : {_id : "\$operator", classes : {\$push : "\$value"}}}])
\$addToSet	Push values to a result array without duplicates	db.docx.aggregate([{\$group : {_id : "\$operator", classes : {\$addToSet : "\$value"}}}])
\$first / \$last	To get the first / last document	db.docx.aggregate([{\$group : {_id : "\$operator", last_class : {\$last : "\$value"}}}])

21. Databases and Collections

- **Drop:** `db.docx.drop()` // removes the collection and its index definitions
- **Create Collection:**

```
// Create collection with a $jsonschema
db.createCollection("contacts", {
  validator: {$jsonSchema: {
    bsonType: "object",
    required: ["gadget"],
    properties: {
      phone: {
        bsonType: "string",
        description: "must be a string and is required"
      },
      email: {
        bsonType: "string",
        pattern: "@mongodb\.com$",
        description: "must be a string and match the regular expression pattern"
      },
      status: {
        enum: [ "Unknown", "Incomplete" ],
        description: "can only be one of the enum values"
      }
    }
  }}
})
```
